As used herein, an atomic coordinate, also referred to herein as a structure coordinate or coordinate, is a mathematical coordinate derived from mathematical equations related to the patterns obtained on diffraction of X-rays by the atoms of a protein crystal. The diffraction data are typically used to calculate an electron density map, such as that shown in Fig. 1, which is used to establish the positions of the individual atoms within the unit cell of the crystal. A model that substantially represents the atomic coordinates specified in Table 1 includes not only models that literally represent the coordinates but also models representing a coordinate transformation of such atomic coordinates, for example, by changing the spatial orientation of the coordinates.

Additional embodiments of the present invention include 3-D models of extracellular domains of FceRIa proteins that substantially represent the atomic coordinates specified in Table 5, Table 6, Table 7 or Table 8, each of which is at the end of the Examples section. Similarly, a model that substantially represents the atomic coordinates specified in Table 5, Table 6, Table 7 or Table 8 includes not only models that literally represent the coordinates but also models representing a coordinate transformation of such atomic coordinates.

The present invention also includes a 3-D model that is a modification of a 3-D model that substantially represents the atomic coordinates specified in Table 5, Table 6, Table 7 or Table 8. As used herein, a modification, also referred to herein as a model modification, is a model that represents a protein that binds to a Fc domain of an antibody. A model modification includes, but is not limited to: a refinement of the model that substantially represents the atomic coordinates specified in Table 1, Table 5, Table 6, Table 7 or Table 8; a model representing any fragment of a protein having the atomic coordinates specified in Table 1, Table 5, Table 6, Table 7 or Table 8 that binds to a Fc domain of an antibody; a model based on other FceRIa protein crystals, such as a model based on one or more of the crystals disclosed in the Examples; a model produced using homology modeling techniques to, for example, incorporate all or any part of the amino acid sequence of another FcR into a 3-D model of the extracellular domain of the model substantially representing the atomic coordinates specified in Table 1, Table 5, Table 6, Table 7 or Table 8 or incorporate all or any part of the amino acid sequence of a FceRIa protein into a 3-D model of another FcR; and a modification representing a FcR

with an altered function, which preferably can be used to design a mutein with an improved function compared to an unmodified protein. As used herein, the term unmodified protein refers to a protein that has not been intentionally subjected to either random or site-directed (i.e., targeted) mutagenesis.

A model of the present invention can be represented in a variety of forms 5 including, but not limited to, listing the coordinates of all atoms comprising the model, providing a physical 3-D model, imaging the model on a computer screen, providing a picture of said model, and deriving a set of coordinates based of a picture of the model, for example by extracting coordinates from a picture or placing a similar immunoglobulin domain into the 3-D model of human Fc ϵ RI α_{1-176} protein form M1, 10 FceRI α_{1-176} protein form M2, FceRI α_{1-172} protein form T1, FceRI α_{1-172} protein form T2, or FceRIa₁₋₁₇₂ protein form H1 and deriving a model of the similar domain. Physical 3-D models are tangible and include, but are not limited to, stick models and space-filling models. The phrase "imaging the model on a computer screen" refers to the ability to express (or represent) and manipulate the model on a computer screen using appropriate 15 computer hardware and software technology known to those skilled in the art. Such technology is available from a variety of sources including, for example, Evans and Sutherland, Salt Lake City, Utah, Biosym Technologies, San Diego, CA, Tripos, Inc., and Molecular Simulations Inc. The phrase "providing a picture of the model" refers to the ability to generate a "hard copy" of the model. Hard copies include both motion and still pictures. Computer screen images and pictures of the model can be visualized in a number of formats including, but not limited to, electron density maps, ribbon diagrams, space-filling representations, α carbon traces, topology diagrams, lists of interatomic vectors, phi/psi/chi angle representations of the coordinates, and contact maps, examples of some of which are in the Figs. Representations of the model can include the entire 25 model or portions thereof.

In one embodiment, a model of the present invention identifies the solvent accessibility of amino acid residues of the corresponding protein. The solvent accessibilities of the amino acids in human $FceRI\alpha_{1-176}$ protein (form M1) are indicated in Table 2.

Table 2. PhFceRI α_{1-176} , Form M1, residue exposure

The solvent accessibilities of the amino acids in human FcεRIα protein forms T1, T2, M2 and M1 are indicated in Tables 9, 10, 11, and 12 respectively, each of which is at the end of the Examples section.

Residues that are solvent accessible are important as they represent amino acids
that are on the external surface of the protein and, as such, may be involved in binding of
a FcR to an antibody and as such be useful in designing proteins with an enhanced
binding activity or in identifying compounds that inhibit such binding. In addition,
solvent accessible residues can represent targets for modification to produce a FcR with
improved function. Such analysis also identifies residues in the interior, or core, of the
protein. Such residues can also be targeted to produce proteins with improved functions,
such as enhanced stability. A model of the present invention also provides additional
information that is not available from other sources. For example, a model can identify
the crystal contacts between crystals and predict the location of the IgE binding domain,
including those amino acids that actually form contacts with a Fc domain of an IgE
antibody, such as those in the binding face of the FcεRIα protein. A model can also
identify the amino acids in the interface between domain 1 and domain 2 (i.e., the D1D2
interface), as well as those in the cleft formed between the two domains.

One embodiment of the present invention is a model that represents a protein that binds to a Fc domain of an IgE antibody with an affinity that is at least equivalent to the affinity of the extracellular domain of human FceRI\alpha for any one of the following IgE antibodies: a human IgE antibody, a canine IgE antibody, a feline IgE antibody, an equine IgE antibody, a rat IgE antibody, and a murine IgE antibody. Such a model can represent an extracellular domain of a human FceRI\alpha protein, a canine FceRI\alpha protein, a feline FceRI\alpha protein, an equine FceRI\alpha protein, a murine FceRI\alpha protein, and a rat FceRI\alpha protein. Such a model can also represent a protein with altered substrate specificity, preferably designed based on a model of the present invention. WO 98/23964, *ibid.*, reports the ability of an isolated human FceRI\alpha protein to bind to canine, feline and equine IgE antibodies. Models of the present invention can be used to design a FcR with increased affinity for an antibody of a species other than self, such as, but not limited to, a human FceRI\alpha with increased affinity for a canine, feline or equine IgE antibody.

The present invention includes a model that represents a FcR that binds to an antibody of its respective class (i.e., IgE, IgG, IgM, IgA or IgD antibody class). Also included is a model that represents a FcR designed to bind to an antibody of a class other than the class to which the protein naturally binds. Such a model of the present invention can be produced, for example, by incorporating all or any part of the amino acid sequence of the other FcR into a 3-D model of the extracellular domain of a human FcεRIα protein. Such an embodiment includes any model that specifically incorporates any Ig domains that are placed in an orientation (packing interfaces and bend angles) that is based on the structure of the FcεRIα. A preferred model of the present invention represents a FcR that binds to an IgE antibody or to an IgG antibody. In one embodiment, a model of the present invention is a 3-D model of an extracellular antibody binding domain of a FcR other than human FcεRIα, such as of a FcR that binds to an IgG antibody. Such proteins and models thereof can be designed by homology modeling by, for example, altering the substrate specificity of a FcεRIα protein such that the altered protein binds an IgG antibody.

A preferred modified model of the present invention is a model that has a 3-D structure comprising atomic coordinates that have a root mean square deviation of protein backbone atoms of less than 10 angstrom when superimposed, using backbone atoms, on the 3-D model substantially represented by the atomic coordinates specified in Table 1, Table 5, Table 6, Table 7 or Table 8, and more particularly atomic coordinates specified in Table 1. Preferably such a model has a 3-D structure comprising atomic coordinates that have a root mean square deviation of protein backbone atoms of less than 8 angstroms, preferably less than 7 angstroms, preferably less than 6 angstroms, preferably less than 5 angstroms, preferably less than 4 angstroms, preferably less than 3 angstroms, preferably less than 2 angstroms, and preferably less than 1 angstroms, when superimposed, using backbon3 atoms, on the 3-D model substantially represented by the atomic coordinates specified in Table 1, Table 5, Table 6, Table 7, or Table 8, and more particularly atomic coordinates specified in Table 1. In this embodiment, such a model represents a FcR that binds to an antibody. The backbone atoms are those atoms that form the backbone, or 3-D folding pattern, of the model. As such, backbone atoms are the base residues of amino acids, i.e., nitrogen, carbon, the alpha carbon and oxygen.

10

15

20

30

Also preferred is a model modification having an amino acid sequence that shares at least about 30%, preferably at least about 40%, more preferably at least about 45%, more preferably at least about 50%, more preferably at least about 60% and even more preferably at least about 80% amino acid sequence homology, with a human FceRIα protein, as determined using the program ALIGN with default parameters, optimal global alignment of two sequences with no short-cuts. It is to be noted that, using the same program and parameters, the extracellular domain of a human FceRIα protein (i.e., soluble human FceRIα protein) shares about 48% identity with feline and rat soluble FceRIα proteins, about 49% with a murine soluble FceRIα protein, about 50% identity with a canine soluble FceRIα protein, and about 60% identity with an equine soluble FceRIα protein. A preferred model of the present invention represents an IgE binding domain, i.e., a region that binds to an IgE antibody.

One embodiment of the present invention is a 3-D model of a human FceRIa protein produced by a method that includes the steps of: (a) crystallizing an extracellular domain of a human FceRIa protein, such as, but not limited to a protein having amino acid sequence SEQ ID NO:2 or SEQ ID NO:4; (b) collecting X-ray diffraction data from the crystallized protein; and (c) determining the model from the X-ray diffraction data, preferably in combination with an amino acid sequence of the protein. A protein for crystal formation can be produced using a variety of techniques well known to those skilled in the art. As disclosed herein, a human FceRIa protein to be crystallized is preferably produced in recombinant insect cells transformed with a gene encoding an extracellular domain of a human FceRIa protein, such as a baculovirus genetically engineered to produce the protein. The purity of the FceRIa protein must be sufficient to permit the production of crystals that can be analyzed by X-ray crystallography to a resolution that permits determination of a 3-D model of the protein. Preferably the resolution is at least about 4 angstroms (i.e., 4 angstroms or better), more preferably at least about 3.5 angstroms, more preferably at least about 3 angstroms, more preferably at least about 2.5 angstroms, more preferably at least about 2 angstroms and even more preferably at least about 1.5 angstroms. Methods to obtain such purity levels are well known to those skilled in the art.

As disclosed herein, a preferred method to crystallize a FceRIa protein is by vapor distillation. Particularly preferred methods are disclosed in the Examples. It should be appreciated that the present invention also includes other methods known to those skilled in the art by which the protein can be crystallized.

3-D models of some proteins have been determined; see, for example, Blundell et al., *Protein Crystallography*, Academic Press, London, 1976. However, as discussed herein, elucidation of the crystal structure of the extracellular domain of the human FcεRlα was difficult. In one embodiment, crystal structure determination includes obtaining high-resolution data using synchrotron radiation. Such data can be collected, for example, at the Stanford Synchrotron Source Laboratory, Palo Alto, CA, or the Advanced Photon Source at Argonne National Laboratories, Argonne, IL. Additional locations to collect such data include, but are not limited to, Brookhaven, NY, and Japan. In one embodiment, diffraction data from native and heavy-atom treated crystals provide an initial image of the protein structure which is refined into an electron density map. Details regarding data collection and interpretation are provided in the Examples section.

One embodiment of the present invention is a method to produce a 3-D model of a FceRI\(\alpha\) protein that includes positioning amino acid representations (i.e., representing amino acids) of the protein at substantially the coordinates listed in Table 1, Table 5, Table 6, Table 7, or Table 8. That is, knowledge of the coordinates of the protein permits one skilled in the art to produce a model of the protein using those coordinates. Such a model, or any model which is essentially represented by a simple coordinate transformation of the coordinates specified in Table 1, Table 5, Table 6, Table 7, or Table 8, can be represented in a variety of methods as heretofore disclosed and is included in the present invention.

In another embodiment, a model of the present invention can be refined to obtain an improved model, which is an example of a model modification, also referred to as a modified model. Refining methods can include, but are not limited to, further data collection and analysis; data collection from frozen crystals; introduction of solvent molecules to the structure; clarification of secondary structure; and analyses of crystallized complexes between a FcR and an antibody or inhibitory compound. An

5

15

20

additional model refinement method includes analyzing a 3-D model to predict amino acid residues that if replaced are likely to yield proteins with at least one improved function, effecting at least one such replacement, determining whether the activity of the modified protein agrees with the prediction, and refining the model as necessary.

Methods to determine whether the modification agrees with prediction include producing the modified protein and performing assays with that modified protein to determine if the protein does indeed exhibit the improved function(s), such as desired activity, stability and solubility properties. Assays to measure such functions are well known in the art; examples of several such assays are disclosed herein.

Another embodiment of the present invention is a modified 3-D model that 10 represents a FcR other than a human FcεRIα protein represented by the 3-D model the coordinates of which are listed in Table 1, Table 5, Table 6, Table 7, or Table 8. Preferably the amino acid sequence of the protein to be modeled is known. In such a case, the modified model can be produced using the technique of homology modeling, preferably by incorporating (e.g., grafting, overlaying or replacing) all or any portion of the amino acid sequence of the other FcR into the 3-D model of the human FceRIa protein to produce the modified model which comprises the other FcR. General techniques for homology modeling, also referred to as molecular replacement, have been disclosed in, for example, Greer, 1990, Proteins: Structure, Function, and Genetics 7, 317-334; Havel et al., 1991, J. Mol. Biol. 217, 1-7; Schiffer et al., 1990, Proteins: Structure, Function, and Genetics 8, 30-43; and Lattman, 1985, Methods Enzymol 115, 55-77. However, such technology has not been applied to FcRs since, until the present invention, no 3-D model of any FcR was available. Thus, the present invention now allows the solving of the structures of a number of other natural and mutated forms of 25 FcRs or any other protein with significant amino acid homology, especially to the functional Ig domains of the human FceRIa protein.

In one embodiment, a model of a FcR, such as, but not limited to a FcεRIα protein, is produced by extracting the 3-D coordinates from a published figure or building a 3-D model with atoms from other Ig domains wherein the Ig domains are oriented as predicted for a human FcεRIα₁₋₁₇₆ protein or a FcεRIα₁₋₁₇₂ protein. For example, a model of the present invention can be produced by orienting two known Ig

domains into a bent confirmation similar to that of the two domains of the human FceRIa protein. Such a model is referred to as a model in which domain 1 and domain 2 are oriented in a manner as specified by the structural coordinates listed in Table 1, Table 5, Table 6, Table 7, or Table 8. This model can then be used in further molecular replacement methods. Such methods can include the steps of (a) orienting the model by three rotations; and (b) translating the model in one to three directions to produce additional model modifications.

Suitable FcRs for which a 3-D model can be determined using homology modeling include any mammalian FcR, such as a protein that binds to IgE, IgG, IgM, IgA or IgD antibodies. Preferred is a protein that binds to an IgE antibody or an IgG antibody. Preferred FcRs that bind to IgE include human, canine, feline, equine, murine and rat FccRIa proteins. The present invention also includes the use of other Ig domains to produce models of the present invention.

One embodiment of the present invention is a 3-D model of a FcR having an improved function compared to an unmodified protein as well as a method to produce such a modified model. Such an improved function includes, but is not limited to, enhanced activity, enhanced stability and enhanced solubility. Such a modified model can be produced by replacing at least one amino acid based on information derived from analyzing the 3-D model of a FceRI α protein, such as the model of a human FceRI α_{1-176} protein or a $FceRIa_{1-172}$ protein, such that the replacement leads to a protein with an improved function. As used herein, a replacement refers to an (i.e., one or more) amino acid substitution, insertion, deletion, inversion and/or derivatization (e.g., acetylation, glycosylation, phosphorylation, PEG modification, biotinylation, and covalent attachment of other ligands or other compounds to the protein. In one embodiment, synthetic chemical methods are used to produce either a fragment or the entire protein to, for example, introduce non-natural amino acids or other chemical compounds into the structure of a FcR. For example, based on a structure of the present invention, one can design synthetic peptides or larger proteins that could be linked to produce an intact protein with IgE binding activity, the structure allowing one to design the start and stop points for these peptides, e.g., at surface accessible loops. In accordance with the present invention, an amino acid that is substituted or inserted can be a natural amino

25

25

30

acid or an unnatural amino acid, including a derivitized amino acid. Methods to identify regions in the protein that, if changed, yield a protein with an improved function are disclosed below.

The present invention includes use of a 3-D model of the present invention to identify a compound that inhibits binding between a FcR and an antibody. The advantages of using a 3-D model to identify inhibitory compounds are multi-fold in that the model depicts the site at which a Fc domain of an antibody binds to its FcR, i.e., the antibody-binding domain, also referred to as the antibody binding site. As such, a large number of potential inhibitory compounds can be initially analyzed without having to perform in vitro or in vivo laboratory studies. As used herein, methods to identify inhibitory compounds include, but are not limited to, designing inhibitory compounds based on the 3-D model of a FcR, probing such a 3-D model with compounds that are potential inhibitors in order to identify those compounds that are actually inhibitory of the binding of an antibody to its FcR, screening a compound data base using such a 3-D model to identify compounds that inhibit such binding, and combinations thereof. Methods to use 3-D models to design, probe for, or screen for suitable inhibitory compounds are known to those skilled in the art. In particular, there are a number of computer programs that enable such methods. See, for example, PCT Publication No. WO 95/35367, by Wilson et al., published December 28, 1995.

An inhibitory compound can be any natural or synthetic compound that inhibits the binding of an antibody to a FcR. Examples include, but are not limited to, inorganic compounds, oligonucleotides, proteins, peptides, antibodies, antibody fragments, mimetics of peptides or antibodies (such as, mimetics of antibody or receptor binding sites), and other organic compounds. Compounds can inhibit binding in either a competitive or non-competitive manner and can either interact at the binding site or allosterically. An inhibitory compound should be capable of physically and structurally associating with a FcR and/or an antibody such that the compound can inhibit binding between the two entitites. As such, an inhibitory compound is preferably small and is of a structure that effectively prevents or disrupts binding. Inhibitory compounds can be identified in one or multiple steps. For example, a compound initially identified that inhibits binding between an antibody and FcR to some extent can be used as a lead to

design, probe or screen for a compound with improved characteristics, such as greater efficacy, safety, solubility, etc. A preferred inhibitory compound is a compound that is efficacious when administered to an animal in an amount that results in a serum concentration of from about 1 nanomolar (nM) to 100 micromolar (μ M), with a concentration of from about 10 nM to 10 μ M being more preferred.

One embodiment of the present invention is a method to identify a compound that inhibits the binding between an IgE antibody and a FceRIa protein. Such a method includes the step of using a 3-D model substantially representing the atomic coordinates specified in Table 1, Table 5, Table 6, Table 7, or Table 8 to identify such a compound. Included in the present invention are inhibitory compounds that interact directly with 10 the IgE binding domain or the receptor binding domain of the IgE antibody as well as compounds that interact indirectly with an FceRIa protein, such as compounds that interact with the D1D2 interface, with the cleft between D1 and D2, with a region not consisting of a N-linked glycosylation site, with a region suggested by a combination of 3-D model and mutagenesis analysis to indirectly affect antibody binding, a region suggested by homology with other FcERIa proteins of other species, a region suggested by homology with other FcRs. In a preferred embodiment, an inhibitory compound interacts with at least one of the following regions of a model representing a FceRIa protein: a A'B loop of D1, a EF loop of D1, a BC loop of D2, a C strand of D2, a CC' loop of D2, a C'E loop of D2, a F strand of domain D2, a FG loop of D2, and a 20 tryptophan-containing hydrophobic ridge. It is to be noted that the A'B and EF loops of D1 are immediately adjacent to the IgE binding domain in D2 and as such are predicted, for the first time, by the model to be good targets for inhibitory compounds. In a preferred embodiment, an inhibitory compound of the present invention interacts with at least one amino acid that is a crystal contact as predicted by the atomic coordinates listed in Table 1, Table 5, Table 6, Table 7 or Table 8. Inhibitory compounds of the present invention preferably interact with at least one of the following amino acid residues: amino acid 87, 110, 113, 115, 117, 118, 120, 121, 122, 123, 128, 129, 131, 149, 153, 154, 155, 156, 157, 158, and 159 of SEQ ID NO:2 or SEQ ID NO:4, as well as any surface residue within about 10 angstroms of any of the listed amino acids. More 30

20

25

30

preferred is an inhibitory compound that interacts with at least one amino acid that is a crystal contact predicted to also be part of the IgE binding domain. Particularly preferred are amino acids 87, 117, 121, 123, 128, 159 of SEQ ID NO:2 or SEQ ID NO:4 as well as any surface residue within about 10 angstroms of amino acids 87, 117, 121, 123, 128, 159 of SEQ ID NO:2 or SEQ ID NO:4. In one embodiment, an inhibitory compound of the present invention is a peptide corresponding to at least a portion of any of the identified regions or a derivative thereof, such as a peptide mimetic or other compound that mimics that peptide. Preferred is a peptide corresponding to at least a portion of the FG loop of D2, or a derivative thereof, such as a peptide mimetic or other compound that mimics that peptide.

One embodiment of a method to identify a compound that inhibits the binding between an IgE antibody and a FceRI\(\alpha\) protein includes the steps of: (a) generating a model substantially representing the atomic coordinates listed in Table 1, Table 5, Table 6, Table 7, or Table 8, or a model of an IgE binding domain thereof, on a computer screen; (b) generating the spacial structure of a compound to be tested; and (c) testing to determine if the compound interacts with said IgE binding domain, wherein such an interaction indicates that the compound is capable of inhibiting the binding of an IgE antibody to a FceRI\(\alpha\) protein. In a preferred embodiment, step (a) includes the step of identifying one or more amino acid(s) in the IgE binding domain of the model that interact directly with the Fc domain of an IgE antibody when the Fc domain binds to the IgE binding domain. Preferably a compound to be tested will interact directly with one or more of those amino acid(s). Preferred amino acids with which an inhibitory compound should interact are disclosed herein.

The present invention also includes inhibitory compounds isolated in accordance with the methods disclosed herein. Methods to produce such compounds in quantities sufficient for use, for example, as protective agents (e.g., preventatives or therapeutics) are known to those skilled in the art. It should also be appreciated that it is within the scope of the present invention to expand the use of models of the present invention to produce models of any suitable FcRs (i.e., model modifications) and to identify compounds that inhibit the binding of antibodies to such FcRs.

The present invention also includes use of a 3-D model of the present invention to rationally design and construct modified forms of FcRs that have one or more improved functions, such as, but not limited to, increased activity, increased stability and increased solubility compared to an unmodified FcR. Muteins of the present invention include full-length proteins as well as fragments (i.e., truncated versions) of such proteins.

One embodiment of the present invention is a FcR that comprises a mutein that binds to a Fc domain of an antibody. Such a mutein has an improved function compared to a protein comprising SEQ ID NO:2 or SEQ ID NO:4. Examples of such an improved function include, but are not limited to, increased stability, increased affinity for an Fc domain of an antibody, altered substrate specificity, and increased solubility. Such a mutein can be produced by a method that includes the steps of: (a) analyzing a 3-D model substantially representing the atomic coordinates specified in Table 1, Table 5, Table 6, Table 7, or Table 8 to identify at least one amino acid of the protein represented by the model which if replaced by a specified amino acid would effect the improved function of the protein; and (b) replacing the identified amino acid(s) to produce a mutein having the improved function. Knowledge of the coordinates allows one to target specific residues, e.g. in the hydrophobic core or on the surface, to generate an accessible set of variants that can then be selected for a particular property, e.g. high stability, high affinity, altered substrate specificity, or other desirable properties (i.e., improved functions). Without the coordinates, one would have to analyze an extraordinarily large number of variants, e.g., on the order of ~1011 possibilities. The structure, in contrast, allows one to pick the most relevant residues for selecting a desired property by, for example, phage display or other methods. In a preferred embodiment, replacement of one or more amino acids does not substantially disrupt the 25 3-D structure of the protein; i.e., the modified protein, or mutein, is still capable of binding to the Fc domain of an antibody. A preferred mutein is a FcR that binds to a Fc domain of an IgE antibody, although the invention also covers muteins binding to other classes of antibodies.

20

In one embodiment, a mutein of the present invention has increased stability 30 compared to its unmodified counterpart. As used herein, increased stability refers to the

15

20

25

30

ability of a mutein to be more resistant, for example, to higher or lower temperature, to more acidic or basic pH, to higher or lower salt concentrations, to oxidation and/or reduction, to deamidation, to other forms of chemical degradation and to proteolytic degradation compared to unmodified FcR. Increased stability can also refer to the ability of a mutein of the present invention to be stable for a longer period of time either during storage (i.e., to have a longer shelf life) or during use (i.e., to have a longer half-life under reaction conditions) than does an unmodified protein. Muteins of the present invention can also exhibit a decreased entropy of unfolding, thereby stabilizing the proteins. Increased stability can be measured using a variety of methods known to those skilled in the art; examples include, but are not limited to, determination of melting temperature, thermal denaturation, pressure denaturation, enthalpy of unfolding, free energy of the protein, or stability in the presence of a chaotropic agents such as urea, guanidinium chloride, guanidinium thiocyanate, etc. A preferred mutein of the present invention has a melting temperature substantially higher than that of an unmodified FcR. Preferably the melting temperature of a mutein is at least about 1°C higher, and more preferably at least about 10°C higher than the melting temperature of the corresponding unmodified protein. Also preferred is a mutein having binding activity over a pH range that is at least about 1 pH unit higher and/or lower than the active pH range of the corresponding unmodified protein.

Another embodiment of the present invention is a mutein that exhibits increased affinity for a Fc domain of an antibody compared to its unmodified counterpart. As used herein, a mutein having increased affinity is a FcR that exhibits a higher affinity constant (K_A) or lower dissociation constant (K_D) than its unmodified counterpart. Such a higher affinity constant can be achieved by increasing the association rate (k_A) between the mutein and the Fc domain and/or decreasing the dissociation rate (k_A) between the mutein and the Fc domain. A preferred mutein of the present invention has a K_A for a Fc domain of at least about 3 x 10° liters/mole (M^{-1}) , which is equivalent to a K_D of less than or equal to about 3.3 x 10° moles/liter (M). More preferred is a mutein having a K_A for a Fc domain of at least about 2 x 10° M^{-1} , and even more preferably of at least about 1 x 10° M^{-1} . Also preferred is a mutein having a K_A for a Fc domain of at least about 1 x 10° liters/mole-second as well as a mutein having a K_A for a Fc domain of less

than or equal to $3 \times 10^{-5}/\text{second}$. More preferred is a mutein having a k_z for a Fc domain of at least about 3×10^5 liters/mole-second, and even more preferably of 1×10^6 liters/mole-second. Also preferred are muteins having a k_d for a Fc domain of less than or equal to $1 \times 10^{-5}/\text{second}$ or even more preferably less than or equal to $3 \times 10^{-4}/\text{second}$. A preferred Fc domain is that of an IgE antibody. Methods to measure such binding constants is well known to those skilled in the art; see, for example, Cook et al., 1997, *ibid.*, which reports the following values for the binding of human FceRI α protein to human IgE: k_{a1} of $3.5 (\pm 0.9) \times 10^5 \, \text{M}^{-1} \text{s}^{-1}$; k_{a2} of $8.6 (\pm 3.5) \times 10^4 \, \text{M}^{-1} \text{s}^{-1}$; k_{d1} of $1.2 (\pm 0.1) \times 10^{-2} \, \text{s}^{-1}$; k_{d2} of $3.2 (\pm 0.8) \times 10^{-5} \, \text{s}^{-1}$; k_{A1} of $2.0 \times 10^7 \, \text{M}^{-1}$; k_{A2} of $2.9 \times 10^9 \, \text{M}^{-1}$.

Another embodiment of the present invention is a mutein that exhibits altered substrate specificity compared to its unmodified counterpart. A mutein exhibiting altered substrate specificity is a mutein that binds with increased affinity to a Fc domain of an antibody class or antibody species of a different type than that normally bound by its unmodified counterpart. In one embodiment, a mutein of a human FceRIa protein with altered substrate specificity is a FcR that binds with increased affinity to a IgE antibody of another mammal, such as, but not limited to, a canine, feline, equine, murine, or rat IgE antibody. In another embodiment, a mutein of a human FceRIa protein with altered substrate specificity is a FcR that binds with increased affinity to an antibody of another class, such as IgG, IgM, IgA, or IgD, with IgG being preferred. Such a mutein can also show altered species substrate specificity. Methods to determine whether a mutein exhibits altered substrate specificity are well known to those skilled in the art.

Yet another embodiment of the present invention is a mutein that exhibits increased solubility compared to its unmodified counterpart. Such a protein is less likely to form aggregates. Methods to determine whether a mutein exhibits increased solubility are well known to those skilled in the art.

As disclosed herein, the 3-D model representing a FceRI α protein is advantageous in determining strategies for producing muteins having an improved function, e.g., for identifying targets to modify in order to obtain muteins having improved functions. Examples of targets are as follows. A key feature of the human FceRI α_{1-176} protein or the FceRI α_{1-172} protein is the crystal contacts in five space groups,

10

10

20

25

30

a subset of which are predicted to interact directly with a Fc domain of an IgE antibody. Such contacts are included in the IgE binding domain which is unique for human FceRIa in that the domain includes a tryptophan-containing hydrophobic ridge positioned on the top face of the crystal structure (i.e., amino acids W87, W110, W113, and W156 of SEO ID NO:2 or SEQ ID NO:4) and an FG loop comprising amino acids from 155 to 158 of SEQ ID NO:2 or SEQ ID NO:4 that protrudes above the interface in an unusual manner. Another key feature is the interface between domain 1 and domain 2 (i.e., the D1D2 interface) which includes amino acids 12, 13, 14, 15, 16, 17, 18, 20, 84, 85 and 86 in D1 and 87, 88, 89, 90, 91, 92, 93, 95, 104, 106, 108, 110, 111, 161, 163, 164, and 165 in D2 of SEQ ID NO:2 or SEQ ID NO:4. Also important are the two domains themselves: D1 includes amino acids 1 through 86 of SEQ ID NO:2 or SEQ ID NO:4; and D2 includes amino acids 87 through 176 of SEQ ID NO:2 or amino acids 87 through 172 of SEQ ID NO:4. Another important feature is the cleft between D1 and D2, which can be identified using the coordinates. Other areas of interest include the hydrophobic core which can be identified using the coordinates, the A'B loop of D1, which includes amino acids 18 and 19, the EF loop of D1, which includes amino acids 59-63, the BC loop of D2, which includes amino acids 110-114, the C strand of D2, which includes amino acids 114-123, the CC' loop of D2, which includes amino acids 123-125, the C'E loop of D2, which includes amino acids 127-134, in the different confirmations observed in the five crystal forms, and the F strand of D2, which includes amino acids 147-155 of SEQ ID NO:2 or SEQ ID NO:4. Yet another striking feature is the finding that the amino and carboxyl termini of the human $FceRIa_{1-176}$ protein are only 10 angstroms apart.

In accordance with the present invention, a mutein having an improved function can be produced by a method that includes replacing at least one amino acid based on information derived from analyzing a 3-D model of the present invention to produce the mutein having the improved function. Knowledge of the structure of the extracellular domain of a human FceRIa protein crystal, for example, permits the rational design and construction of modified forms of the protein by permitting the prediction and production of substitutions, insertions, deletions, inversions and/or derivatizations that effect an improved function. That is, analysis of 3-D models of the present invention

WO 00/26246 PCT/US99/26203

-61-

provide information as to which amino acid residues are important and, as such, which amino acids can be changed without harming the protein. In making amino acid replacements, it is preferred to use amino acid replacements that have similar numbers of atoms and that allow conservation of salt bridges, hydrophobic interactions and

5 hydrogen bonds unless the goal is to purposefully change such interactions. The 3-D structure of the human FcεRIα protein suggests that large deletions may not be desirable, particularly due to the relation between the various domains of the protein and the observation that most of the structure is well ordered in the crystal. An exception to this is the non-constrained loops of D1, which apparently could be deleted or shortened without harming the protein's function. These loops span amino acids 31-35 and 70-74 of SEQ ID NO:2 or SEQ ID NO:4.

It is to be appreciated that although one amino acid replacement capable of improving the function of a protein can substantially improve that function, more than one amino acid replacement can result in cumulative changes depending on the number and location of the replacements. For example, although one amino acid replacement capable of substantially increasing the stability of a protein can increase the melting temperature of that modified protein by about 1°C, about 5 to about 6 replacements may increase the melting temperature of the resultant protein by about 10°C.

15

20

In accordance with the present invention, the 3-D model of the human FceRIa protein has been analyzed, using techniques known to those skilled in the art, to determine the accessibility of the amino acids represented within the model to solvent. Such information is provided in, for example, Table 2, Table 9, Table 10, Table 11, and Table 12.

A number of methods can be used to produce muteins of the present invention.

One method includes the steps of: (a) analyzing a 3-D model substantially representing the coordinates specified in Table 1, Table 5, Table 6, Table 7, or Table 8 to identify at least one amino acid of the modeled protein which if replaced by a specified amino acid would effect an improved function; and (b) replacing the identified amino acid(s) to produce a mutein having that improved function. In one embodiment, a method to

produce a mutein includes the steps of (a) comparing a key region of a model of a human FceRIa protein with the amino acid sequence of a FcR having an improved function

20

25

30

compared to the unmodified FceRIa protein in order to identify at least one amino acid segment of the FcR with the improved function that if incorporated into the FccRIa protein represented by the model would give the FceRIa protein the improved function; and (b) incorporating the segment into the FceRIa protein, thereby providing a mutein with the improved function. In another embodiment, a method to produce a protein includes the steps of: (a) using a model representing a human FceRIa protein to identify a 3-D arrangement of residues that can be randomized by mutagenesis to allow the construction of a library of molecules from which a improved function can be selected; and (b) identifying at least one member of the mutagenized library having the improved function. In one example, a mutein is produced by a method that includes the steps of: (a) effecting random mutagenesis of nucleic acid molecules encoding a target of a FceRIa protein as identified by analyzing a model of that protein, such as an IgE binding domain; (b) cloning such mutagenized nucleic acid molecules into a phage display library, wherein said phage display library expresses the target; and (c) identifying at least one member of the library that expresses a target with an improved function, such as an antibody binding domain exhibiting increased affinity for an antibody. As stated above, the model allows the use of this technique in a straightforward manner that could not be accomplished in the absence of the model. It is to be also noted that these methods can also be used with other models of the present invention to produce muteins of the present invention.

The present invention includes a number of methods, based on analysis of a 3-D model of the present invention, to replace (i.e., add, delete, substitute, invert, derivatize) at least one amino acid residue in the protein represented by the model in order to produce a mutein of the present invention. Such methods include, but are not limited to:

(a) replacing at least one amino acid in at least one non-constrained loop of domain 1 in an area proximal to the FceRI gamma chain putative binding site; (b) joining an aminoterminal amino acid residue to a carboxyl-terminal amino acid residue of an extracellular domain of a FcεRIα protein; (c) replacing at least one amino acid site with an amino acid suitable for derivatization; (d) replacing at least one pair of amino acids of the protein with a cysteine pair to enable the formation of a disulfide bond that stabilizes the protein; (e) removing at least a portion of the region between the B strand and C strand

of domain 1; (f) removing at least a portion of the region between the C strand and E strand of domain 1; (g) replacing at least one amino acid in the IgE binding domain in order to increase the affinity between an IgE antibody and the protein; (h) replacing at least one amino acid of the protein with an amino acid such that the replacement decreases the entropy of unfolding of the protein; (i) replacing at least one asparagine or glutamine of the protein with an amino acid that is less susceptible to deamidation than is the amino acid to be replaced; (j) replacing at least one methionine, histidine or tryptophan with an amino acid that is less susceptible to an oxidation or reduction reaction than is the amino acid to be replaced; (k) replacing at least one arginine of the protein with an amino acid that is less susceptible to dicarbonyl compound modification than is the amino acid to be replaced; (1) replacing at least one amino acid of the protein susceptible to reaction with a reducing sugar sufficient to reduce protein function with an amino acid less susceptible to that reaction; (m) replacing at least one amino acid of the protein with an amino acid capable of increasing the stability of the inner core of the protein; (n) replacing at least one amino acid of the protein with at least one N-linked glycosylation site; (o) replacing at least one N-linked glycosylation site of the protein with at least one amino acid that does not comprise an N-linked glycosylation site; and (p) replacing at least one amino acid of the protein with an amino acid that reduces aggregation of the protein.

Amino acid replacements can be carried out using recombinant DNA techniques known to those skilled in the art, including site-directed mutagenesis (e.g., oligonucleotide mutagenesis, random mutagenesis, polymerase chain reaction (PCR)-aided mutagenesis, gapped-circle site-directed mutagenesis) or chemical synthetic methods of a nucleic acid molecule encoding the desired protein, such as, but not limited to a human FceRIa protein, followed by expression of the mutated gene in a suitable expression system, preferably an insect, mammalian, bacterial, yeast, insect, or mammalian expression system. See, for example, Sambrook et al., *ibid*.

One embodiment of the present invention is a mutein in which at least one amino acid in at least one non-constrained loop of a FceRIa protein is replaced in order to improve a function of the protein. Finding that the human FceRIa protein had such loops was surprising, and it is believed, without being bound by theory, that a mutein in

30

15

which at least a portion of at least one such loop is replaced, would at least exhibit enhanced stability. In a preferred embodiment, at least a portion of one or more of such loops is (are) deleted. Preferred loops to replace are in domain 1 (i.e., spanning amino acids 31-35 and 70-74 of SEQ ID NO:2 or SEQ ID NO:4), preferably in an area proximal to the FceRI gamma chain putative binding site, i.e., the site on the FceRIα protein to which the gamma chain of the high affinity Fc epsilon receptor is thought to bind. In a preferred embodiment, one or more amino acids is replaced to make loops shorter, but including 1 or 2 hydrophobic residues to pack toward the protein interior and at least one hydrophilic residue to maintain solubility.

Another embodiment of the present invention is a mutein of the extracellular 10 domain of a FceRIa protein in which an N-terminal (amino-terminal) amino acid residue is joined, preferably covalently, to a C-terminal (carboxyl-terminal) amino acid residue in order to improve a function of the protein. Finding that the N-termini and C-termini of the human FceRIa protein were only 10 angstroms apart was quite surprising. Without being bound by theory, it is believed that such a mutein would at least exhibit 15 enhanced stability. Furthermore, a covalent linker used to join the termini could also include a substance useful, for example, to anchor a mutein on a surface, as would be useful, for example, in a diagnostic assay, or to label the mutein. For a protein consisting of SEQ ID NO:2, a preferred N-terminal residue is an amino acid residue at position 1, 2, or 3 of SEQ ID NO:2, and a preferred C-terminal residue is an amino acid 20 residue at position 174, 175, or 176 of SEQ ID NO:2. Covalent linkage can be accomplished by methods known to those skilled in the art, such as, but not limited to, adding one or more N-terminal and C-terminal cysteines and crosslinking them with chemical compounds, adding additional residues in the coding sequence to allow the formation of a disulfide bond, or adding one or more lysines and coupling them through a 10 angstrom linker, and including non-natural amino acid analogues by synthetic methods or by a combination of biosynthetic and organosynthetic methods. Examples of a substance to add to a covalent linker includes: ligands useful in allowing for the attachment of a mutein to a surface, such as biotin and related compounds, avidin and related compounds, metal binding compounds, sugar binding compounds. 30 immunoglobulin binding domains, and other tag domains; and detectable markers, such

as enzyme labels, physical labels, radioactive labels, fluorescent labels, chemiluminescent labels, and chromophoric labels. Examples include, but are not limited to, alkaline phosphatase, horseradish peroxidase, digoxygenin, luciferase, other light-generating enzymes and magnetic beads. It is also to be noted that ligands can function as detectable markers.

Another embodiment of the present invention is a mutein in which at least one amino acid is replaced with an amino acid suitable for derivatization. Muteins in which at least one amino acid is replaced with an amino acid suitable for derivatization include proteins that are chemically modified (e.g., a lysine already existing on the protein is modified) as well as those in which an amino acid residue is replaced with a different amino acid residue (e.g., a glycine with a lysine) as well as proteins to which a substance is added, preferably to the amino or carboxyl terminus of the protein. Examples of such substances include ligands and detectable markers as disclosed above. Preferable amino acids to replace include residues that are solvent exposed (e.g., those listed in Table 2, Table 9, Table 10, Table 11, or Table 12), but that are preferably not within about 10 angstroms of the IgE binding domain. In one embodiment, a glycosylation site, or other solvent exposed site, is replaced with a charged or polar residue to increase solubility or create more stable muteins. Glycosylation sites in human FceRIa protein include amino acids 21, 42, 50 74, 135, 140, and 166 of SEQ ID NO:2 or SEQ ID NO:4. A preferred amino acid to use as a replacement, or to chemically modify directly, includes a cysteine or a lysine, with a cysteine being preferred. Compounds to use in chemical derivatizations are known to those skilled in the art; cysteines can, for example, be derivatized with maleimides.

Another embodiment of the present invention is a mutein in which a pair of

amino acids have been replaced with a cysteine pair in order to improve the function of
the mutein, at least by increasing stability. Cysteine pairs can be substituted into a

FceRIa protein at any two residue positions identified with available programs and
algorithms that would allow the formation of an undistorted disulfide bridge. In one
embodiment, a serine and lysine near the termini of the protein is each replaced with a

cysteine. In another embodiment, cysteine pairs are replaced with other amino acids,
such as serines to eliminate non-essential disulfide bonds.

5

10

15

Another embodiment of the present invention is a mutein in which at least one amino acid is replaced in the region between the B strand and C strand of domain 1 and/or the region between the C and E strand of domain 1. In a preferred embodiment, at least a portion of such a region is deleted.

Another embodiment of the present invention is a mutein in which at least one 5 amino acid is replaced in the IgE binding domain in order to increase the affinity between an IgE antibody and the protein. Preferred residues to replace are in or near the IgE binding domain, or IgE binding site, as determined by analysis of the 3-D model. Such residues are preferably within about 10 angstroms of residues identified by mutagenesis and further shown by model to be in an IgE binding site. Examples of such 10 residues include amino acids 87, 110, 113, 115, 117, 118, 120, 121, 122, 123, 128, 129, 131, 149, 153, 154, 155, 156, 157, 158, and 159 of SEQ ID NO:2 or SEQ ID NO:4, and amino acids within 10 angstroms of such listed amino acids. In one embodiment, preferred amino acids to replace include amino acids 87, 115, 117, 118, 120-123, 128, 129, 131, 149, 153, 155 and 159 of SEQ ID NO:2 or SEQ ID NO:4 as well as any 15 surface residue within about 10 angstroms of any of the listed amino acids, with amino acids 87, 117, 121, 123, 128, 159 of SEQ ID NO:2 or SEQ ID NO:4 as well as any surface residue within about 10 angstroms of amino acids 87, 117, 121, 123, 128, 159 of SEQ ID NO:2 or SEQ ID NO:4 being particularly preferred. It is to be noted that amino acids 115, 118, 120, 131, 149 and 155 of SEQ ID NO:2 or SEQ ID NO:4 are buried, and 20 that amino acids that are partially buried or glycine include residues 122, 129 and 153. Additional amino acid residues to target include those in the A'B loop of D1, and EF loop of D1. Note that these residues are not the same as those shown in mutation studies to affect IgE binding since some of those mutants have mutations in amino acids that are internal to the protein; this finding can only be made by analysis of a model of the 25 present invention.

Another embodiment of the present invention is a mutein in which at least one amino acid is replaced with an amino acid capable of increasing the stability of the inner core or surface of the protein. Preferred amino acids to replace are hydrophilic residues located in the hydrophobic core of the protein and/or hydrophobic amino acids at the protein surface that are not within about 10 angstroms of the IgE binding domain

residues of D1 or D2. Preferred amino acids to replace into the hydrophobic core are hydrophobic residues such as, but not limited to, tryptophan, leucine, isoleucine, valine and alanine, as well as space filling amino acids, such as other aromatic amino acids. Preferred amino acids to replace onto the surface are polar amino acids, such as, but not limited to, glutarnic acid, glutarnine, aspartic acid, asparagine, histidine and serine. Muteins having one or more such amino acid replacements would exhibit at least increased stability and/or reduced aggregation. Additional preferred amino acid replacements are those that introduce salt bridges at the protein surface to stabilize protein folds. It is noted that the cysteines at positions 26 and 68 of SEQ ID NO:2 or SEQ ID NO:4 form a disulfide bond in domain 1 that is somewhat exposed to solvent, 10 depending especially on the conformation of the D1 "30 loop" (i.e., amino acids 31-35 of SEQ ID NO:2 or SEQ ID NO:4). In one embodiment, changes in neighboring residues can be made in, for example, residues 1-5, 27-37, 49-52, or 69-75, to bury this disulfide from exposure to solvent. For example, phage display of receptors with randomized mutations in the 30 loop, might be useful for selecting receptors that react less well with reducing reagents and have a more stable D1 core.

Another embodiment of the present invention is a mutein in which at least one amino acid is replaced with an amino acid that decreases the entropy of unfolding of the protein. The entropy of unfolding of a protein can be measured and compared to that of another protein using techniques known to those skilled in the art. A number of methods known to those skilled in the art can be used to reduce the number of protein conformations possible in the unfolded state, thereby improving the ability of the protein to fold correctly. One embodiment of the present invention for decreasing the entropy of unfolding includes replacing at least one amino acid of the protein with a specified amino acid in order to maintain certain desirable phi and psi backbone conformation angles in the protein; see, for example, PCT International Publication No. WO 89/01520, by Drummond et al., published February 23, 1989. For example, a proline residue in a protein constrains the backbone conformation to certain restricted angles. Analysis of a 3-D model of a protein of the present invention permits the identification of candidate replacement positions in the protein that have the conformation expected for a proline, but that do not have a proline in them. Such knowledge is used to

20

25

15

20

30

introduce prolines into such candidate replacement positions to "anchor" the resultant mutein in the desired conformation. The 3-D model also permits the identification of candidate replacement sites that if replaced with a proline do not substantially disrupt the 3-D structure of the resultant protein. Similarly, glycines in appropriate positions can be replaced with an amino acid having a β carbon atom or a branched β carbon atom, preferably an alanine, in order to stabilize the backbone of the protein.

Another embodiment of the present invention is a mutein in which at least one asparagine or glutamine is replaced with an amino acid that is less susceptible to deamidation. Preferred amino acids to replace include solvent accessible asparagines and glutamines.

Another embodiment of the present invention is a mutein in which at least one methionine, histidine or tryptophan is replaced with an amino acid that is less susceptible to an oxidation or reduction reaction. Preferred amino acids to replace include M98, H70, and H41. It would not be preferred to replace any of the tryptophans, nor H108 or H134 of SEQ ID NO:2 or SEQ ID NO:4.

Another embodiment of the present invention is a mutein in which at least one arginine is replaced with an amino acid that is less susceptible to dicarbonyl compound modification. Although R174 could be changed, it would probably not be preferable to change amino acids at the D1D2 interface or near the IgE binding site, such as amino acids 15, 106, or 111 of SEQ ID NO:2.

Another embodiment of the present invention is a mutein in which at least one amino acid that is susceptible to reaction with a reducing sugar sufficient to reduce protein function is replaced with an amino acid that is less susceptible to such a reaction. For example, lysines, glutamines and asparagines that could react with a sugar, such as galactose, glucose or lactose can be replaced with non-reactive amino acids.

Another embodiment of the present invention is a mutein in which one or more N-linked glycosylation sites are added to or removed from the protein, preferably by substitution with an appropriate amino acid. A FceRIa protein with additional N-linked glycosylation sites is more soluble. The ability to design a FceRIa protein having fewer, or no, N-linked glycosylation sites is also valuable as production of such a protein from production run to production run is likely to be more uniform. One embodiment is a

FcεRIα mutein with no N-linked glycosylation sites that is stable, active, and soluble. Such a protein has an advantage of being produced in *E*. coli at low cost. In one embodiment, one or more exposed hydrophobic amino acids are changed to charged residues that form salt bridges to stabilize the protein fold and make it soluble. It is to be noted that the glycosylation sites that appear to be most often observed in the different crystal structures in the same conformation are the carbohydrate attached to positions 42 and 166 of SEQ ID NO:2 or SEQ ID NO:4. The carbohydrate attached to position 42 always appears to cover the phenylalanine at position 60 of SEQ ID NO:2 or SEQ ID NO:4. As such, one embodiment of the present invention is to remove the glycosylation site at position 42, e.g., by substitution with a suitable amino acid. This embodiment has the additional advantage that the resultant mutein has an exposed phenylalanine at position 60, thereby leading to increased IgE binding activity.

Another embodiment of the present invention is a mutein in which at least one amino acid is replaced with an amino acid that reduces aggregation and increases solubility of the protein, such as, for example, replacing one or more hydrophobic residues on the surface with one or more hydrophilic residues. Other examples of such amino acids to replace are disclosed herein.

Another embodiment of the present invention to enhance stability is the addition of polyethylene glycol (PEG) groups to a FcR protein, i.e., to produce a "pegylated" FcR protein. In one embodiment, the PEG group(s) can substitute for carbohydrate group(s) due to removal of one or more N-glycosylation sites. Such PEG group(s) can be attached to easily modifiable residues, such as cysteines or lysines, on the surface of the protein, such residues identifiable by analysis of a 3-D model of the present invention.

Another embodiment of the present invention is a mutein that comprises a FcR having a substance, such as a ligand or detectable marker, attached to an amino acid of the protein such that the substance does not substantially interfere with the antibody binding activity of the protein. The substance is attached in such a manner that the substance is also capable of performing its function, such as binding to a second member of a ligand pair or enabling detection of the protein. The FcR to which a substance is attached can be either an unmodified protein or a mutein of the present invention. Suitable attachment sites can be identified using 3-D models of the present invention.

15

20

15

20

25

30

Preferred attachment sites include solvent exposed amino acids, such as those listed in Table 2, Table 9, Table 10, Table 11, or Table 12. Substances can be attached, or conjugated, to the protein using techniques known to those skilled in the art. It is to be appreciated that a preferred method to attach a substance to an amino acid is to modify that amino acid to have a reactive attachment site, such as is present on cysteine and lysine amino acids. As such, an attachment site comprising a solvent exposed amino acid refers to the nature of the amino acid prior to any modification required for attachment. Examples of suitable substances to attach to a FcR include any compound capable of binding to or reacting with another substance, such as those described for attachment to a covalent linker.

It is to be appreciated that muteins of the present invention can include amino acids which are not modified because they would negatively impact the function of the protein. Such amino acids can be identified using a 3-D model of the present invention.

It should also be appreciated that it is within the scope of the present invention to expand the use of models of the present invention to produce models of and make modifications to any suitable FcRs or other Ig domain-containing proteins to produce muteins having a desired function.

The present invention also includes nucleic acid molecules that encode muteins of the present invention as well as recombinant molecules and recombinant cells that include such nucleic acid molecules. Methods to produce such proteins are also disclosed herein.

The present invention includes an isolated FcεRIα protein that consists of SEQ ID NO:2, i.e., PhFcεRIα₁₋₁₇₆. Also included in the present invention is a protein consisting of an extracellular domain of a FcεRIα protein that is structurally homologous to an isolated FcεRIα protein consisting of SEQ ID NO:2. As used herein, a protein that is structurally homologous to PhFcεRIα₁₋₁₇₆ is a protein that (a) includes both D1 and D2 domains, (b) shares at least about 30%, and preferably at least about 40%, amino acid sequence identity with SEQ ID NO:2, as determined using a ALIGN with default parameters, optimal global alignment of two sequences with no short-cuts, (c) displays a substantially equivalent affinity for an IgE antibody as does a complete extracellular domain of the corresponding FcεRIα protein, and (d) produces crystals having sufficient

quality to enable structure determination. Examples of such proteins include a human FcεRIα protein having SEQ ID NO:4, i.e., PhFcεRIα₁₋₁₇₂ and a human FcεRIα protein having an amino acid sequence that spans from amino acid 3 through amino acid 174 of SEQ ID NO:2, i.e., PhFcεRIα₃₋₁₇₄. It is to be noted that these examples are provided to clarify the definition of a structurally homologous FcεRIα protein and are not intended to limit the scope of such proteins. That is, a FcεRIα protein that is structurally homologous to PhFcεRIα₁₋₁₇₆ is any mammalian FceRIα protein having the listed characteristics. Preferred are human, canine, feline, equine, murine and rat proteins that are structurally homologous to PhFceRIα₁₋₁₇₆. Also included herein are nucleic acid molecules to encode such proteins as well as recombinant molecules and recombinant cells that include such nucleic acid molecules. Methods to produce such proteins are also disclosed herein. Preferably such proteins are produced in insect cells.

The present invention also includes a FceRI\alpha protein consisting of SEQ ID NO:4 except that the isoleucine at position 170 has been replaced by a cysteine. Also included in the present invention is a protein consisting of an extracellular domain of a FceRI\alpha protein that is structurally homologous to an isolated FceRI\alpha protein consisting of SEQ ID NO:4 except that the isoleucine at position 170 has been replaced by a cysteine.

The present invention also includes the following novel structures as identified by a 3-D model of the present invention: a crystal contact cluster, preferably involved in IgE binding; a tryptophan-containing hydrophobic ridge; a FG loop in D2; a D1D2 interface; a cleft between D1 and D2; a domain 1; a domain 2; a hydrophobic core; a A'B loop of D1; a EF loop of D1; a BC loop of D2; a C strand of D2; a CC' loop of D2; a C'E loop of D2; and a strand of D2. Also included herein are nucleic acid molecules to encode such structures as well as recombinant molecules and recombinant cells that include such nucleic acid molecules. Also included are methods to produce such structures and models thereof.

The present invention also includes isolated nucleic acid molecules encoding proteins of the present invention, including, but not limited to, proteins comprising unmodified extracellular domains of FcRs, novel structures within such proteins, and muteins. As used herein, an isolated nucleic acid molecule encoding a protein is a nucleic acid molecule that has been removed from its natural milieu. As such, "isolated"

15

20

does not reflect the extent to which the nucleic acid molecule has been purified. An isolated nucleic acid molecule can be DNA, RNA, or derivatives of either DNA or RNA.

A nucleic acid molecule encoding a mutein of the present invention can be produced by mutation of parental protein genes (e.g., unmodified or previously modified protein-encoding genes, or portions thereof) using recombinant DNA techniques heretofore disclosed or by chemical synthesis. Resultant mutein nucleic acid molecules can be amplified using recombinant DNA techniques known to those skilled in the art, such as PCR amplification or cloning (see, for example, Sambrook et al., *ibid.*), or by chemical synthesis. A mutein can also be produced by chemical modification of a protein expressed by a nucleic acid molecule encoding an unmodified protein or mutein-encoding gene.

Proteins of the present invention can be produced in a variety of ways, including production and recovery of recombinant proteins and chemical synthesis. In one embodiment, a protein of the present invention is produced by culturing a cell capable of expressing the protein under conditions effective to produce the protein, and recovering the protein. A preferred cell to culture is a recombinant cell that is capable of expressing the protein, the recombinant cell being produced by transforming a host cell with one or more nucleic acid molecules of the present invention. Transformation of a nucleic acid molecule into a host cell can be accomplished by any method by which a nucleic acid molecule can be inserted into a cell. Transformation techniques include, but are not limited to, transfection, electroporation, microinjection, lipofection, adsorption, and protoplast fusion. A recombinant cell may remain unicellular or may grow into a tissue, organ or a multicellular organism. Transformed nucleic acid molecules of the present invention can remain extrachromosomal or can integrate into one or more sites within a chromosome of a host cell in such a manner that their ability to be expressed is retained.

Suitable host cells to transform include any cell that can be transformed. Host cells can be either untransformed cells or cells that are already transformed with at least one nucleic acid molecule. Host cells of the present invention can be endogenously (i.e., naturally) capable of producing a protein of the present invention, but such cells are not preferred. Host cells of the present invention can be any cell that when transformed with a nucleic acid molecule of the present invention are capable of producing a protein of the

PCT/US99/26203

present invention, including bacterial, yeast, other fungal, insect, animal, and plant cells. Preferred host cells include bacterial, yeast, insect and mammalian cells, and more preferred host cells include Escherichia, Bacillus, Saccharomyces, Pichia, Trichoplusia, Spodoptera and mammalian cells. Particularly preferred host cells are Trichoplusia ni cells, Spodoptera frugiperda cells, and Chinese hamster ovary cells.

A recombinant cell is preferably produced by transforming a host cell with a recombinant molecule comprising a nucleic acid molecule of the present invention operatively linked to an expression vector containing one or more transcription control sequences. The phrase operatively linked refers to insertion of a nucleic acid molecule into an expression vector in a manner such that the molecule is able to be expressed when transformed into a host cell. As used herein, an expression vector is a DNA or RNA vector that is capable of transforming a host cell, of replicating within the host cell, and of effecting expression of a specified nucleic acid molecule. Expression vectors can be either prokaryotic or eukaryotic, and are typically viruses or plasmids. Expression vectors of the present invention include any vectors that function (i.e., direct gene expression) in recombinant cells of the present invention, including in bacterial, yeast, other fungal, insect, animal, and plant cells. Preferred expression vectors of the present invention can direct gene expression in bacterial, yeast, insect and mammalian cells.

Nucleic acid molecules of the present invention can be operatively linked to expression vectors containing regulatory control sequences such as promoters, operators, repressors, enhancers, termination sequences, origins of replication, and other regulatory control sequences that are compatible with the host cell and that control the expression of the nucleic acid molecules. In particular, recombinant molecules of the present invention include transcription control sequences. Transcription control sequences are sequences which control the initiation, elongation, and termination of transcription. Particularly important transcription control sequences are those which control transcription initiation, such as promoter, enhancer, operator and repressor sequences. Suitable transcription control sequences include any transcription control sequence that can function in at least one of the recombinant cells of the present invention. A variety of such transcription control sequences are known to those skilled in the art. Preferred

5

10

20

25

transcription control sequences include those which function in bacterial, yeast, insect and mammalian cells.

It may be appreciated by one skilled in the art that use of recombinant DNA technologies can improve expression of transformed nucleic acid molecules by manipulating, for example, the number of copies of the nucleic acid molecules within a host cell, the efficiency with which those nucleic acid molecules are transcribed, the efficiency with which the resultant transcripts are translated, and the efficiency of posttranslational modifications. Recombinant techniques useful for increasing the expression of nucleic acid molecules of the present invention include, but are not limited to, operatively linking nucleic acid molecules to high-copy number plasmids, integration of the nucleic acid molecules into one or more host cell chromosomes, addition of vector stability sequences to plasmids, substitutions or modifications of transcription control signals (e.g., promoters, operators, enhancers), substitutions or modifications of translational control signals (e.g., ribosome binding sites, Shine-Dalgarno sequences), modification of nucleic acid molecules of the present invention to correspond to the codon usage of the host cell, deletion of sequences that destabilize transcripts, and use of control signals that temporally separate recombinant cell growth from recombinant protein production during fermentation. The activity of an expressed recombinant protein of the present invention may be improved by fragmenting, modifying, or derivatizing nucleic acid molecules encoding such a protein.

In accordance with the present invention, recombinant cells can be used to produce proteins by culturing such cells under conditions effective to produce such a protein, and recovering the protein. Effective conditions to produce a protein include, but are not limited to, appropriate media, bioreactor, temperature, pH and oxygen conditions that permit protein production. An appropriate medium refers to any medium in which a cell of the present invention, when cultured, is capable of producing the protein. An effective medium is typically an aqueous medium comprising assimilable carbohydrate, nitrogen and phosphate sources, as well as appropriate salts, minerals, metals and other nutrients, such as vitamins. The medium may comprise complex nutrients or may be a defined minimal medium. Cells of the present invention can be cultured in conventional fermentation bioreactors, which include, but are not limited to,

15

20

batch, fed-batch, cell recycle, and continuous fermentors. Culturing can also be conducted in shake flasks, test tubes, microtiter dishes, and petri plates. Culturing is carried out at a temperature, pH and oxygen content appropriate for the recombinant cell. Such culturing conditions are well within the expertise of one of ordinary skill in the art.

Depending on the vector and host system used for production, resultant proteins may either remain within the recombinant cell; be secreted into the fermentation medium; be secreted into a space between two cellular membranes, such as the periplasmic space in E. coli; or be retained on the outer surface of a cell or viral membrane. The phrase "recovering the protein" refers simply to collecting the whole fermentation medium containing the protein and need not imply additional steps of separation or purification. Proteins of the present invention can be purified using a variety of standard protein purification techniques, such as, but not limited to, affinity chromatography, ion exchange chromatography, filtration, electrophoresis, hydrophobic interaction chromatography, gel filtration chromatography, reverse phase chromatography, chromatofocusing and differential solubilization.

The present invention also includes isolated (i.e., removed from their natural milieu) antibodies that selectively bind to a FcR of the present invention (i.e., anti-FcR antibodies). As used herein, the term "selectively binds to" FcR refers to the ability of antibodies of the present invention to preferentially bind to specified proteins of the present invention. Binding can be measured using a variety of methods standard in the art including enzyme immunoassays (e.g., ELISA), immunoblot assays, etc.; see, for example, Sambrook et al., ibid. Isolated antibodies of the present invention can include antibodies in a bodily fluid (such as, but not limited to, serum), or antibodies that have been purified to varying degrees. Antibodies of the present invention can be polyclonal 25 or monoclonal. Functional equivalents of such antibodies, such as antibody fragments and genetically-engineered antibodies (including single chain antibodies or chimeric antibodies that can bind to more than one epitope) are also included in the present invention. Antibodies can be produced using methods known to those skilled in the art. A preferred method to produce antibodies of the present invention includes (a) administering to an animal an effective amount of a protein of the present invention to produce the antibodies and (b) recovering the antibodies. In another method,

20

25

30

antibodies of the present invention are produced recombinantly using techniques as heretofore disclosed to produce proteins of the present invention. Antibodies raised against defined proteins can be advantageous because such antibodies are not substantially contaminated with antibodies against other substances that might otherwise cause interference in a diagnostic assay or side effects if used in a therapeutic composition.

Antibodies of the present invention have a variety of potential uses that are within the scope of the present invention. Examples of such uses are disclosed in WO 98/27208, *ibid.*, see, for example, page 24.

A FcR of the present invention can include chimeric molecules comprising at least a portion of a FcR that binds to an antibody and a second molecule that enables the chimeric molecule to be bound to a substrate in such a manner that the antibody receptor portion binds to the antibody in at least as effective a manner as a FcR that is not bound to a substrate. An example of a suitable second molecule includes a portion of an immunoglobulin molecule or another ligand that has a suitable binding partner that can be immobilized on a substrate, e.g., biotin and avidin, or a metal-binding protein and a metal (e.g., His), or a sugar-binding protein and a sugar (e.g., maltose).

The present invention includes uses of proteins, antibodies and inhibitory compounds of the present invention for the diagnosis and treatment of allergy and the regulation of other immune responses in an animal.

One embodiment is a therapeutic composition comprising at least one of the following therapeutic compounds: an inhibitory compound of the present invention, a mutein of the present invention, or an antibody of the present invention. Also included is a method to protect an animal from allergy or other abnormal immune responses. Such a method includes the step of administering a therapeutic composition of the present invention to the animal. As used herein, the ability of a therapeutic composition of the present invention to protect an animal from allergy or other abnormal immune responses refers to the ability of that composition to, for example, treat, ameliorate or prevent allergy or other abnormal immune responses. General characteristics of therapeutic compositions and methods to produce and use such therapeutic compositions are disclosed, for example, in WO 98/27208, *ibid.*, see, for example, page 39-47. It is to

WO 00/26246 PCT/US99/26203

-77-

be noted that although the compositions and methods disclosed in WO 98/27208, *ibid.*, relate to feline FccRIa proteins, they are also applicable to therapeutic compositions of the present invention. Therapeutic compositions of the present invention are advantageous because they can be derived from analysis of 3-D models of the present invention and have improved functions, such as efficacy and safety.

Another embodiment is a diagnostic reagent comprising a mutein of the present invention. As used herein, a diagnostic reagent is a composition that includes a mutein that is used to detect allergy or other abnormal immune responses in an animal. Also included in the present invention are methods, including in vivo methods and in vitro 10 methods, to (a) detect allergy or other abnormal immune response, or susceptibility thereto, in an animal, comprising use of a diagnostic reagent comprising a mutein of the present invention and (b) to enhance the performance of an IgE binding assay, said method comprising incorporating into the assay a mutein of the present invention. General characteristics of diagnostic reagents and methods to produce and use such diagnostic reagents are disclosed, for example, in WO 98/27208, ibid., see, for example, page 2-39. It is to be noted that although the reagents and methods disclosed in WO 98/27208, ibid., relate to feline FcεRIα proteins, they are also applicable to diagnostic reagents, kits and detection methods of the present invention. Muteins of the present invention are advantageous in such applications because of their enhanced affinity for antibodies, altered specificity, enhanced solubility and/or enhanced stability, 20 enabling for example use in otherwise adverse conditions and longer shelf-life.

The following examples are provided for the purposes of illustration and are not intended to limit the scope of the invention.

EXAMPLES

Example 1

5

This Example describes the production of a FceRIa nucleic acid molecule, a recombinant molecule, a recombinant cell, a recombinant virus, and a FceRIa protein of the present invention.

A number of human FcεRIα proteins of variable lengths (i.e., 171, 172, and 176 amino acids) were produced in a variety of cell lines (i.e., Chinese hamster ovary cells, *Pichia pastoris* yeast, *Spodoptera frugiperda* (*Sf*9) insect cells and *Trichoplusia ni* (Hi-5) insect cells). Due to a number of factors, however, including protein length, solubility, and extent and variability of glycosylation, only one FcεRIα protein was useful in producing a crystal of sufficient quality for the first determination of a model of an extracellular domain of a FcεRIα protein. The production of this protein is disclosed below.

A nucleic acid molecule comprising the first 176 amino acids of the mature form
of the human FcεRIα protein, nucleic acid molecule and protein designated herein as
nhFcεRIα₁₋₅₂₈ and PhFcεRIα₁₋₁₇₆, respectively, was produced as follows. An *Eco*RI-*Hind*III fragment from plasmid EdpC20 (Blank et al., *ibid.*) containing the human
FcεRIα signal sequence and residues 1-172 of the mature human FcεRIα protein was
ligated to two oligonucleotides coding for residues 172-176 of the mature protein and
two stop codons. The two oligonucleotides, having nucleic acid sequences of 5'
AGCTCCGCGT GAGAAGTAAT AAG 3' (SEQ ID NO:5) and 5' GATCCTTATT
ACTTCTCACG CGG 3' (SEQ ID NO:6), had *Hind*III and *Bam*HI overhangs when
annealed together, which permitted the ligation of nhFcεRIα₁₋₅₂₈ into *Eco*RI and *Hind*III
cleaved baculovirus transfer vector pVL1392 (available from Pharmingen, San Diego,
CA) to produce recombinant molecule pVL1392-nhFcεRIα₁₋₅₂₈. The resultant construct
was verified by DNA sequencing.

Recombinant virus was produced as follows. Recombinant molecule pVL1392-nhFcεRIα₁₋₅₂₈ was co-transfected with a linear Baculogold baculovirus DNA (available from Pharmingen) into *S. frugiperda* Sf9 cells to form recombinant cell *Sf*9:pVL1392-nhFcεRIα₁₋₅₂₈ which was cultured to produce recombinant virus, namely BV:pVL1392-nhFcεRIα₁₋₅₂₈ using techniques known to those skilled in the art. Supernatants of

transfected Sf9:pVL1392-nhFceRIa₁₋₅₂₈ cells were amplified once in TNM-FH medium (available from Pharmingen), followed by a second amplification in serum-free medium (SF-900, available from Gibco, Gaithersburg, MD) in a final volume of about 500 milliliters (ml). For Sf9:pVL1392-nhFceRIa₁₋₅₂₈ cells grown in shaker flasks, TNM-FH medium was supplemented with pluronic F-68 (available from Pharmingen). For each virus stock used in protein production, the optimal amount of virus and harvest time post-infection was determined by small scale tests in 50 ml shaker flasks.

Recombinant protein PhFcεRIα₁₋₁₇₆ was produced as follows. *Trichoplusia ni* (Hi-5) cells were infected with recombinant virus BV:pVL1392-nhFcεRIα₁₋₅₂₈ that had been produced as described above to produce recombinant cell Hi-5:pVL1392-nhFcεRIα₁₋₅₂₈. Recombinant cell Hi-5:pVL1392-nhFcεRIα₁₋₅₂₈ was grown in shaker or spinner flasks for production of PhFcεRIα₁₋₁₇₆. Typical yields of PhFcεRIα₁₋₁₇₆ were about 2 to 12 milligrams per liter (mg/liter) of infected cells 2 to 4 days after infection.

Recombinant protein PhFcεRIα₁₋₁₇₆ was purified as follows. Supernatants from 1.5 to 5 liters of recombinant Hi-5:pVL1392-nhFcεRIα₁₋₅₂₈ cells were collected, filtered through 0.2 micron filters, and loaded directly onto a Mab15-1 (Sechi et al., 1996, *J. Biol. Chem. 271*, 19256-19263) monoclonal antibody column. Supernatants were recirculated over the column at least twice, followed by buffer (100 millimolar (mM) Na, K phosphate, pH 7) washes of about 300 ml, until the absorbance at 280 nanometers (nm) of the cluant returned to zero. PhFceRIα₁₋₁₇₆ was cluted by two urea washes: 100 ml of 5 molar (M) urea in 100 mM phosphate, pH 7.0; then 100 ml of 7 M urea in 100 mM phosphate, pH 7.0; followed by extensive regeneration with 100 mM Na, K phosphate, pH 7.0. The urea cluants were pooled, concentrated to about 25 to 40 ml with an Amicon stirring concentrator, and dialyzed 4 times against 2 liters of 50 mM Tris, pH 7.5. The purity of PhFceRIα₁₋₁₇₆ was verified by SDS-PAGE. Purified PhFceRIα₁₋₁₇₆ was stored at 4°C in the presence of 0.05% sodium azide. Final yield of PhFceRIα₁₋₁₇₆ was about 50% based on an absorption coefficient of 2.6 mg⁻¹ml for the purified protein and the initial total protein estimated using ELISA assays with the initial cell supernatants.

An inhibition-ELISA assay was used to quantitate PhFcεRIα₁₋₁₇₆ expression and yields in initial transfected supernatants, subsequent viral amplifications and large scale protein preparations. In this assay, the binding of Mab15-1 antibody to the plated

25

PhFceRIα₁₋₁₇₆ protein was monitored using a goat anti-mouse-alkaline phosphatase antibody (A-2429, available from Sigma, St. Louis, MO). Unknown samples were used to compete for antibody binding and compared with a standard curve generated in parallel. Fifty microliters (ml or mL) of purified PhFceRIa₁₋₁₇₆ was incubated in microtiter plates overnight at 4°C at a concentration of 1 mg/ml in phosphate-buffered saline. Plates were rinsed with wash buffer containing 20 mM Hepes, pH 7.5, 100 mM NaCl. 0.1% Tween-20 (Hepes/NaCl buffer) and blocked with Hepes/NaCl buffer containing 1% Carnation dry milk. Standard inhibitor samples ranging from 0.1-50 mg/ml of PhFc ϵ RI α_{1-176} in two-fold dilution series were incubated with Mab15-1 (0.1 mg/ml final concentration) and added in duplicate to wells coated with PhFcεRIα₁₋₁₇₆. Standard controls included wells without overnight incubation with PhFceRIa₁₋₁₇₆, and addition of Mab15-1 without inhibiting PhFceRIa₁₋₁₇₆. Secondary antibody in a 1:5000 dilution was incubated after washing for 12 hour at room temperature. Plates were washed and developed using the AP reagent p-nitrophenyl phosphate (PNPP, available from Sigma 104-105). Microplates were read using a Molecular Devices SpectraMax 15 Plus reader at 405 nm.

Example 2

10

20

This Example describes the production of a FceRIa protein crystal of the present invention.

Purified PhFceRIa₁₋₁₇₆, produced as described in Example 1, was concentrated to a final concentration of 20 mg/ml in 20 mM Tris pH 7.5. Crystallization was carried out using the hanging drop method, with a precipitant composed of 100 mM Tris, pH 8.5, 200 mM NaOAc, and 18-24% PEG 4000. Crystals were obtained in 2 to 10 days amidst significant amounts of protein precipitate. At lower PEG concentrations, a different crystal form was observed. The crystals used in the structure determination typically 25 grow as clusters of 3 to 20 crystals that could be separated manually. The crystals belong to the monoclinic space group C2, with cell dimensions of 88.6 x 69.6 x 49.3 angstroms, alpha=gamma=90 degrees, beta=116.7 degrees, with one receptor molecule per asymmetric unit. Such crystals diffracted to a resolution of about 2.4 angstroms. Crystals were harvested into harvest buffer containing 35% PEG 4000, 100 mM Tris pH 30

8.5. It is to be noted that the inventors produced and tested several hundred crystals

using the various other proteins described in Example 1, before successfully obtaining the crystal described immediately above.

Example 3

This Example describes the production of additional FceRIa protein crystals of the present invention.

Nucleic acid molecule nhFcεRIα₁₋₅₁₆, encoding the first 172 amino acids of the human FcεRIα protein was expressed in *T. ni* Hi-5 cells to produce PhFcεRIα₁₋₁₇₂ in a manner similar to that described for the production of PhFcεRIα₁₋₁₇₆ in Example 1.

Purified PhFcεRIα₁₋₁₇₂ was concentrated to a final concentration of 20 mg/ml in 20 mM

Tris pH 7.5. Crystallization was carried out using the hanging drop method, with a precipitant composed of 0.1-0.2 M NaAcetate, 0.1M Na Citrate, pH 5.6, 18-24% PEG, and HECAMEG detergent at it's Critical Micelle concentration (19.5 mM). Crystals were obtained in 2 to 10 days amidst significant amounts of protein precipitate. The crystals belong to the monoclinic space group P6122 with unit cell dimensions of 58 x 58 x 226 angstroms, alpha=beta=90 degrees; gamma=120 degrees, with one receptor molecule per asymmetric unit. Such crystals diffracted to a resolution of about 3.2 angstroms.

Using a different protocol, purified PhFcεRIα₁₋₁₇₆, produced as described in Example 1, was concentrated to a final concentration of 10 mg/ml in 20 mM Tris pH 7.5. Crystallization was carried out using the hanging drop method, with a precipitant composed of 100 mM Tris, pH 7.5, 0-20% isopropanol, and 18-24% PEG 4000. Crystals were obtained in 2 to 10 days amidst significant amounts of protein precipitate. The crystals belong to the monoclinic space group C2, with cell dimensions of 136.02 x 75.01 x 79.28 angstroms, alpha=gamma=90 degrees; beta=117.8 degrees. Such crystals diffracted to a resolution of about 3.0 angstroms.

Example 4

This Example describes the production of a three-dimensional model of the present invention.

For data collection, crystals, produced as described in Example 2, were mounted in nylon loops (available from Hampton-Research, Laguna Niguel, CA) and rapidly cooled in liquid nitrogen after a short (about 30 second) soak in harvest buffer

PCT/US99/26203

supplemented with 14% glycerol. Heavy atom soaks with K₂PtBr₄ and K₃AuCl₃ were done in harvest buffer with 5 mM Pt for 48 hours and 1 mM Au for 18 days. Data were collected at the Stanford Synchrotron Radiation Laboratories (SSRL) 7-1 beamline and at the Dupont-Northwestern-Dow undulator beamline at the Advanced Photon Source at Argonne National Laboratories. The statistics for these data are shown in Table 3.

For the Pt and Au datasets, the wavelength was chosen to be 200 eV above the absorption edge of the metal, in order to maximize the anomalous signal for each heavy atom. Heavy atom data were collected using reverse beam protocols to optimize the anomalous diffraction signal. Diffraction data were collected with a Mar300 Image plate (SSRL) or a MarCCD detector (DND-CAT), and integrated and scaled with DENZO/SCALEPACK; see, Otwinowski et al., 1997, In *Methods in Enzymology: Macromolecular Crystallography*, part A, Academic Press, pp 307-326. The CCP4 suite of programs (Collaborative Computational Project, 1994, *Acta Cryst. D50*, 760-763) was used for further processing and identification of heavy atom sites.

Heavy atom positions were identified from peaks in the anomalous and 10 isomorphous difference patterson maps. Heavy atom positions were refined and phases calculated with the program MLPHARE, followed by solvent flattening and density modification with the program DM (Collaborative Computational Project, 1994, ibid.). The subsequent model was using the CNS program (Brunger et al., 1998, Acta Crystallogr D Biol Crystallogr 54, 905-921) with the combined maximum likelihood 15 and experimental phase target (MLHL). Specifically, the structure of the FceRIa protein PhFcεRIα₁₋₁₇₆ was determined by multiple isomorphous replacement using gold and platinum heavy atom derivatives with the anomalous signal from both derivatives. The data collection and heavy atom phasing statistics are shown in Table 3. The MIRAS phases were used as input to the density modification program DM and the electron density map was of sufficient quality that the entire model except for two flexible loops and five residues at the termini could be built; see Fig. 1A and 1B. The model was further improved by cycles of automated refinement using the program CNS followed by manual rebuilding. The current R-factor and Rfree are 24.2% and 27.1% respectively for all the data to 2.4 angstroms. No electron density was observed for three residues at the N-terminus (1-3) and 2 residues at the C-terminus (175-176), and poor density was observed for two loops (residues 32-35 and 70-73) that are disordered in the crystal. Final statistics for the model are shown in Table 3.

Example 5

This Example describes the structure of a FeeRIa protein predicted by a threedimensional model of the present invention.

A. Overall structure

The model of extracellular domain of the human FceRIa protein, also referred to herein as the hFceRI α model or hFceRI α structure, indicates that PhFceRI α_{1-176} is composed of two immunoglobulin (Ig) domains, D1 and D2, each about 85 residues in 5 length, that are bent at an acute angle relative to each other and form an extended convex surface; see Fig. 2. The domain arrangement generates a flat surface at the top of the receptor that has been implicated in binding to the Fc domain of an IgE antibody. The domains are small compared to canonical variable and constant Ig domains and the shorter sequence is accommodated by truncation of the CC'E crossover region; see Fig. 2. Both domains D1 and D2 of the hFceRIa model are composed of beta-strands 10 AA'BCC'EFG, differing from the previously described I-set domains (Harpaz et al., 1994, J. Mol. Biol. 238, 528-539) by the absence of strand D. The nearly antiparallel domain packing places the A'B, CC' and EF loops of D1 and the BC, C'E and FG loops of D2 near the top of the receptor; see Fig. 2. One feature of the topology is a crossover of the A strand from the ABE sheet to the CC'FG sheet, forming a short segment of parallel beta sheet in an otherwise antiparallel structure; see Fig. 2 and Fig. 3. In D1, the AA' crossover make contacts in the D1D2 interface (see below), while in the D2 domain, residues in the A strand interact with D1; see Fig. 3.

Significant structural differences are also observed between D1 and D2 of the hFceRIa model. The D1 and D2 sequences contain about 28% identical residues and superimpose with an RMS deviation of 1.2 angstroms for the Ca atoms. The F-G strands and loop differ between the two domains. In D2, these strands are longer and the FG loop projects above the D2 domain surface. The C' strands also differ between the two domains. In D2, a series of aromatic residues (tyrosines at positions 120 and 131) 25 form a hydrophobic core that pushes the C' strand and loop away from the C strand, altering the local conformation of this region. The FG loop and C-C' strands of D2 form part of the binding site for IgE (see below).

The tertiary packing arrangement of the hFccRIa D1 and D2 domains is distinct from other tandem Ig domain structures; see Fig. 4. Comparison of the hFceRIa model with other bent two-Ig domain structures reveals a high degree of variability in the bend angles and packing surfaces between domains. A subset of D1 and D2 representative

30

structures of are shown in Fig. 4, including those from human FceRIa (designated as IgE-FcR), the natural killer cell inhibitory receptor, (KIR, Fan et al., 1997, Nature 389, 96-100), the human growth hormone receptor (HGHBP, de Vos et al., 1992, Science 255, 306-312), the interleukin-1 receptor, (IL1R, Vigers et al., 1997, Nature 386, 190-194) and the insect defense protein hemolin (Su et al., 1998, Science 281, 991-995). The structures are oriented similarly with respect to the carboxyl-termini of the two Ig domains being compared. The figures on top show side views and the figures below show top views. The FceRIa and hemolin structures have the most acute angles relating two sequential Ig domains. The top view of these domains shows that the orientation of the hemolin and FccRIa domains are more closely related, but between this selected 10 subset of proteins there is significant variability in the relative orientations of tandem Ig domain structures. The bend angle between domains and domain packing interfaces are clearly unique, and this variation is likely to be important in ligand binding interactions. For example, the FG loop of D2 in hFceRIa is oriented quite differently with respect to D1 residues as compared to the same region of the KIR or HGHBP, thus changing the 15 spatial relationships of D1D2 loops that may be involved in ligand interactions. To the inventors' knowledge, the hFceRIa structure defines a new group of two sequential Ig domain structures that differs from other known tertiary arrangements.

B. The D1D2 interface

The bent shape of the FceRIα structure produces a large interface between the D1D2 domains that buries 1280 Ų of accessible surface area of 28 D1D2 residues. There are 11 residues from the D1 domain (12-18, 20, 84-86) and 17 residues from the D2 domain that are buried at the interface (87-93, 95, 104, 106, 108, 110-111, 161, 163-165). Of these 28 residues, 8 are completely conserved in all human FcgR and FceRIα sequences (corresponding to residues 13, 87, 88, 90, 91, 106, 108, 110 of SEQ ID NO:2); see Fig. 5. These conserved residues form a significant fraction to one side of the buried interface, suggesting that related FcRs would have a similar acute packing of the D1D2 domains as observed in the FceRIα model.

However, 20 residues that form the D1D2 interface in the FceRIa model differ in other FcRs and these differences could alter the relative orientations of the two domains. For example, the conserved tryptophan at position 110 packs against a phenylalanine at

20

position 17 of FcεRIα. In related FcRs, this phenylalanine is changed to a leucine, which may lead to slight alterations in the packing of the two domains. Another central residue in the FcεRIα D1D2 interaction is residue R15, which forms a hydrogen bond with the carbonyl of L90 and is packed against L89, F84, and L165. In related human FcRs, arginine 15 is changed to serine or asparagine, which corresponds to a significant volume and charge change at the center of the D1D2 interaction. Since the interactions of the FcR with antibody are near the D1D2 interface, alterations in residues at the interface might influence receptor specificity. Other residues that are variable amongst the FcR sequences in the region of the D1D2 could also perturb the D1D2 interactions.

The bent hFceRIα structure generates a cleft between the two domains that is near the trans-membrane anchor at the C-terminus of D2; see Fig. 2. This cleft is located far from the IgE binding site identified by mutagenesis studies (see below). Although there is no known function attributed to this region, while not being bound by theory, it is believed that this region could be a site of interaction with the extracellular regions of the beta or gamma subunits of the receptor. It has been suggested that interactions between the FcgRI and FcgRIIIA alpha and gamma subunits increase the binding affinity of the receptor for IgG (Miller et al., 1996, *J. Exp. Med. 183*, 2227-2233). Although the extracellular regions of the human FceR gamma chain are short (about 5 to 7 amino acids), these regions could potentially interact with the D1D2 cleft and thereby affect the affinity of the receptor for antibody. In addition, recent binding studies with recombinant, soluble FcεRIα and IgE have demonstrated a 10-fold lower affinity than had previously been determined in cell-binding assays (Cook et al., 1997, *ibid.*).

The human FcεRIα protein PhFcεRIα₁₋₁₇₆ is the most highly glycosylated protein structure solved by X-ray crystallography to date, having seven N-linked glycosylation sites in 176 amino-acid residues. The intact FcεRIα on mast cells is approximately 40% carbohydrate by weight (Kanellopoulos, et al., 1980, E. J. Biol. Chem. 255, 9060-9066); LaCroix, et al., 1993, *ibid.*), with a heterogeneous molecular weight on SDS-PAGE gels of about 50 kilodaltons (kD). Human FcεRIα expressed in insect cells has a molecular weight of about 34 kD as observed using SDS-PAGE, but, based on typical insect cell glycosylation structures (-GlcNAc₂-Man₃-GlcNAc), could be expected to have a

10

20

25

25

30

molecular weight of about 27.5 kD, suggesting the protein is about 30% carbohydrate by weight. While the presence of carbohydrate at the seven N-glycosylation sites is not required for binding to IgE (Letourneur et al., 1995, *ibid.*; Robertson, 1993, *ibid.*; Scarselli et al., 1993, *ibid.*), mutation of these sites or treatment of FceRI-expressing cells with tunicamycin leads to the aggregation of the receptor during biosynthesis.

In the hFceRIa structure, carbohydrate density is observed at three of the seven predicted glycosylation sites. For two of these sites, asparagines 42 and 166, three sugar moieties were built. The carbohydrate at position 42 extends up towards the top of the FceRIa structure, covering residues F60, S63 and V83. The carbohydrate attached to position 166 projects away from the protein surface, potentially as a result of crystal contacts and the modification of the third and sixth positions of the first GlcNac residue. The third carbohydrate attachment site is the arginine at position 21.

Many of the related FcR proteins are also highly glycosylated proteins and the glycosylation sites vary between receptors. Rat and mouse FcεRIα proteins each have six potential N-linked glycosylation sites, of which two sites and one site, respectively are shared in common with the human FcεRIα protein. Comparison of seventeen human and animal FcR sequences identifies twenty-five different potential N-linked carbohydrate attachment sites in related FcRs. The twenty-five sites are distributed evenly between D1 and D2, with fourteen sites in D1 and eleven sites in D2. Five of these sites are relatively well conserved sites in all FcRs (found in > 9/17 sequences analyzed) and they correspond to residues 35, 42, 61, 135, and 142 of SEQ ID NO:2. These sites cover a significant fraction of the FcεRIα surface on both major faces of D1 and D2, placing limitations on the surface available for interactions with antibody.

It is not known why FcRs are so heavily glycosylated. Many potential roles for carbohydrate sites on proteins have been suggested, including specific roles in determining the tertiary (Wyss et al., 1995, Science 269, 1273-1278) or quaternary structures of proteins (Huber et al., 1976, Nature 264, 415-420; Vaughn et al., 1998, Structure 6, 63-73). In the case of the human FcRs, the number of potential N-linked glycosylation sites correlates to some degree with the affinity of the FcR for immunoglobulin. Table 4 shows the number of glycosylation sites in the domains corresponding to the extracellular domain of the human FcεRIα protein along with the

total number of glycosylation sites in parentheses. Affinity data are taken from Ravetch et al., 1998, *ibid.*; Ravetch et al., 1991, *Annu. Rev. Immunol.* 9, 457-492.

In the high affinity FcRs, there are typically 5 to 7 potential N-linked glycosylation sites, whereas in the low affinity FcRs there are as few as two sites. One significant difference in the function of the high and low affinity FcRs is the probability that they will bind antibody in the absence of antigen. The high affinity receptors such as FceRI can bind

IgE prior to interacting with antigens. While not being bound by theory, it is believed that since FcR activation requires crosslinking of receptors, glycosylation might prevent the aggregation of large antibodies at the cell surface bound by FcRs. Crystallization of proteins at lipid/water interfaces can occur readily, and the potentially high local concentrations of membrane-bound antibodies might lead to FcR activation in the absence of antigen. The low affinity IgG receptors interact with antibody-antigen aggregates that can simultaneously bind and activate multiple FcRs. While not being bound by theory, it is believed that glycosylation may not be quite as important for these receptors, since interaction with the antibody could occur after the binding of antigen.

However, it is likely that there are additional explanations for the glycosylation that is observed in the FcRs. The non-human FcRs do not show an obvious correlation of the number of carbohydrate sites and FcR affinity. While not being bound by theory, it is believed that glycosylation might be important in FcR signaling, by orienting receptor:antibody complexes into functional signaling complexes (i.e. by preventing antigen-crosslinked complexes from forming non-functional aggregates). It is known that activation through FcERI is sensitive to some geometrical constraints imposed by antigen crosslinkers, although the nature of these physical constraints is poorly understood. The recent crystal structure determination of an erythropoietin-receptor complex suggests that the orientation of ligand-mediated dimerization of cell-surface receptors may be important in efficient signal transduction (Syed et al., 1998, *Nature* 395, 511-516).

D. Receptor binding site for IgE (IgE binding domain)

A number of mutagenesis studies have been carried out in an effort to elucidate the regions of the FceRI that are critical for the interaction with IgE molecules (Cook et al., 1997, *ibid.*; Hulett et al., 1993, *ibid.*; Hulett et al., 1994, *ibid.*; Hulett et al., 1995; Mallamaci et al., 1993, *ibid.*). These experiments have demonstrated an important

15

20

25

WO 00/26246 PCT/US99/26203

-92-

role for amino acids in the D2 domain of the receptor, although some regions of D1 are also likely to be involved in IgE binding. Studies suggesting that D1 plays a role in IgE binding include the deletion of D1 (Robertson, 1993, *ibid.*; Scarselli et al., 1993, *ibid.*) or substitution with a homologous IgG receptor (Hulett et al., 1994, *ibid.*). These experiments do not determine conclusively whether D1 interacts directly with the IgE or whether D1 indirectly alters the structure of D2 and subsequent interactions with IgE. Analysis of the hFcεRIα model of the present invention is needed to predict important IgE binding regions in the protein. For example, the substitution or elimination of residues at the D1D2 interface can influence D2 interactions with antibody Fc regions.

In addition, there are a number of regions of D1 which have been excluded as determinants of the specificity of the receptor for IgE, since these FcεRIα segments can be substituted by the corresponding residues in the FcgRIIIA protein (Mallamaci et al., 1993, *ibid.*). These residues include segments 25-38, 43-54, 67-79, and 77-86. Substitution of residues 10-21 or 55-67 disrupt the binding of IgE and 5 different monoclonal antibodies, suggesting that residue differences in these segments may affect the folding of hybrid molecules. The 3-D models of the present invention, however, are needed to conduct an amino acid by amino acid analysis of which residues actually directly interact with IgE antibodies.

10

15

20

25

The FcεRIα residues which have been implicated in past studies include residues in the D2 BC loop (amino acid 115), in the C strand (amino acids 117, 118, 120-123), in the C'E loop (amino acids 129, 131), the F strand (amino acids 149, 153) and the FG loop (amino acids 155 and 159) (Cook et al., 1997, *ibid.*; Hulett et al., 1994, *ibid.*; Hulett et al., 1995, *ibid.*). In addition, residues 87 (at the D1D2 interface) and 128 (in the C'E loop) are likely to be part of the IgE interaction site, since mutation of these residues have been shown to influence receptor binding to the IgE point mutant R334A (Cook et al., 1997, *ibid.*). Furthermore, a synthetic peptide corresponding to residues 119-129 has been demonstrated to block IgE binding to the FcεRIα, with an apparent K_D of about 3 mM (McDonnell et al., 1997, *ibid.*; McDonnell et al., 1996, *ibid.*).

Analysis of the hFccRIa model, however, is needed to indicate that of the fifteen residues (i.e., amino acids 87, 115 117, 118, 120-123, 128, 129, 131, 149, 153, 155 and 159), six are buried in the protein core (i.e., amino acids 115, 118, 120, 131, 149, 155)

and predicts that substitution at these positions may lead to indirect structural changes that affect IgE binding. Three of the residues are either partially buried or glycine (i.e., amino acids 122, 129, 153), and substitution may affect the conformation of the local residues. The remaining residues (i.e., amino acids 87, 117, 121, 123, 128, 159) are all exposed amino acids at the FceRIa surface. All of the implicated residues form a contiguous surface extending from the back side of the D2 domain to the top region near the D1D2 interface. Four of the residues are conserved in all human FcRs (i.e., amino acids 87, 118, 149, and 153) and may define a set of common interactions between all FcR receptors and their target Ig molecules.

The hFcεRIα model also indicates that the region of the D2 domain defined by mutagenesis also borders on a number of surface accessible aromatic residues, including four prominent tryptophans at the top of the FcεRIα molecule, namely residues 87, 110, 113, and 156. These four tryptophans form a flat, hydrophobic ridge that neighbors the D2 FG loop. This unusual arrangement of four surface tryptophans probably forms a contact surface for a complementary interaction with an IgE antibody. Tryptophan 87 has already been implicated by mutagenesis studies and tryptophan 156 is prominently displayed at the top of the FG loop. Tryptophan 156 is a glycine in all FcgRs and grafting of residues 154-161 of the FcεRIα FG-loop to FcgRII confers IgE binding. It is to be noted, however, that such a graft does not eliminate IgG binding. The hFcεRIα model predicts that other amino acids, e.g., the tryptophan at residue 87, may be important for antibody class recognition specificity. Other exposed aromatic residues are found concentrated near the IgE binding domain; Fig 6 shows a surface representation of all of the exposed aromatic groups in the hFcεRIα structure, clearly outlining the tryptophan ridge and residues in D2 near the CC'E region.

25 E. Implications for the binding of other FcRs

Since carbohydrate would be expected to disrupt any close-packed protein:protein interface, it is interesting to compare the known carbohydrate sites with the proposed IgE-binding site on the receptor surface as defined by models of the present invention. The positions of the carbohydrate attachment sites for seventeen related FcRs indicated that the N-linked carbohydrate sites delineate a boundary around the proposed IgE binding site. This is consistent with the suggestion that related FcRs share a

10

15

20

30

common binding surface for antibody molecules. Studies of the FcgRII specificity for IgG, for example, have implicated the following residues: amino acids 113-116, 129, 131, 133, 134, 155, 156, and 159-161 (Hulett et al., 1994, *ibid.*; Hulett et al., 1995, *ibid.*). In addition, domain-swap experiments have demonstrated that two of the related FcgRs can form functional hybrid molecules with FcεRIα (Hulett et al., 1995, *ibid.*; Mallamaci et al., 1993, *ibid.*), suggesting that these receptors share a common binding surface with their respective antibody ligands. Once again, however, it should be noted that only with the model can one predict exactly which FcR residues directly interact with an Fc domain of an antibody.

The hFceRIa model indicates that the top of the FcR structure is devoid of carbohydrate-attachment sites in the region of D2 that has been implicated in direct interactions with Ig molecules. The neighboring surface of the D1 domain including loops A'B and EF, are also devoid of carbohydrate and could form part of an extended antibody binding site across the D1D2 interface. If these D1 loops are important in determining the specificity and affinity of the FcR:antibody interaction, one might observe sequence variability between high affinity and low IgG receptors and the IgE receptor. This variability in the human IgG and IgE receptors is shown in Fig. 5. For residues 3-173 of the hFceRIa protein, there are 73 amino acid differences that are unique to the IgE receptor as compared to any of the IgG receptors and these are indicated below the sequence alignments. Of these 73 amino acids unique to the human FceRIα protein, 27 positions are highly variable in the different FcR sequences (> 4/7) different amino acids. There are five regions that stand out with clusters of variable residues: residues 27-30, 47-49, 54-59, 94-98 and 155-159. Residues 155-159 (the FG loop) are highly variable and do at least partially determine the specificity of FcR interactions. It is again to be noted that without the model one cannot determine which regions of sequence variability are important in determining FcR protein functional domains.

Previous experiments have shown that residues 27-30 and 47-49 are not critical for FcR specificity (Mallamaci et al., 1993, *ibid.*), and the presence of glycosylation sites within these segments in related FcRs support the suggestion that these regions are not part of the FcR:antibody interaction. The hFccRIα model indicates that residues 94-98

15

are found in the A' strand near the D1D2 cleft and therefore are not likely to interact with antibody directly, but these residues might influence interactions indirectly by altering the D1D2 packing interface.

The remaining group of highly variable residues (54-59) are in the D1 E strand (see Fig. 7), near the FceRI\alpha binding site as predicted by the hFceRI\alpha model. Residues 54-59 could form a D1 surface of interaction with the Fc domains of antibodies, extending the binding site across both FceRI\alpha domains. This prediction is supported by a study reporting that the exchange of FceRI\alpha residues 55-67 with residues from the FcgRIIIA receptor disrupts the folding of the protein (Mallamaci et al., 1993, *ibid.*), as some of the residue changes form part of the D1 hydrophobic core. The hFceRI\alpha model also predicts that the neighboring D1 A'B loop (residues 18-21) could also form part of an extended surface of interaction with the antibody. Thus, models of the present invention are needed to interpret data from mutagenesis and swapping experiments. F. Stoichiometry of binding between FcR and antibody

The activation of FcR-bearing cells requires crosslinking of the receptors, which leads to the activation of intracellular kinase cascades analogous to those in B and T cells. For both high and low high affinity receptors FceRI and FcgRIII, a stoichiometry of 1:1 is observed between the receptor and the Fc domains of the respective antibodies to which they bind (Ghirlando et al., 1995, *Biochemistry 34*, 13320-13327;

Kanellopoulos et al., 1980, ibid.; Keown et al., 1997, Eur. Biophys. J. 25, 471-476), consistent with a requirement for antigen to cause receptor aggregation and activation.
The binding site on the Fc domain of an IgE antibody for its receptor has been extensively studied by mutagenesis, implicating amino acids in the third constant domain (Ce3) of the IgE (Basu et al., 1993, J. Biol. Chem. 268, 13118-13127; Henry et al., 1997, Biochemistry 36, 15568-15578; Nissim et al., 1991, Embo J. 10, 101-107;

al., 1997, Biochemistry 36, 15568-15578; Nissim et al., 1991, Embo J. 10, 101-107; Presta et al., 1994, J. Biol. Chem. 269, 26368-26373). The structure of the Fc domain of IgE antibodies (also referred to as IgE-Fc domains) has not been experimentally determined, but is homologous to the Fc domain of IgG antibodies (also referred to as IgG-Fc domains), for which a number of crystal structures are available (Harris et al.,

1998, J. Mol. Biol. 275, 861-872; Huber et al., 1976, Nature 264, 415-420). The residues of the IgE-Fc domain implicated in binding to FceRs based on mutagenesis

analysis are shown mapped onto the structure of the IgG-Fc domain in Fig. 8. The site on an IgG-Fc domain to which FcgRI and FcgRII receptors bind has been mapped to a similar, although smaller, surface that primarily includes residues in the hinge region before the Cg2 domain (Canfield et al., 1991, J. Exp. Med. 173, 1483-1491; Duncan et 5 _a., 1988, Nature 332, 563-564; Jefferis et al., 1990, Mol. Immunol. 27, 1237-1240; Lund et al., 1991, J. Immunol. 147, 2657-2662).

An antibody Fc domain is a homodimeric structure that is significantly larger than its respective FcR; see Fig. 8. The observed 1:1 stoichiometry between receptor and antibody indicates that the two-fold symmetry of the Fc domain does not lead to the binding of two FcRs, even with isolated molecules in solution. Without being bound by theory, it is believed that the large and convex nature of the FcR binding surface could span two antibody domains (Cg2 in IgG and Ce3 in IgE) and induce a conformational change in the Fc domain that would prevent the binding of a second FcR to the same antibody. The FcR structure could also form an asymmetric complex with the antibody that sterically blocks the binding of a second FcR, perhaps using the protruding FG loop to block symmetric interactions with the Fc hinge region.

Example 6

10

20

25

This Example describes the production of additional three-dimensional models of the present invention as well as descriptions of FceRIa proteins predicted therefrom.

Production and description of a crystal of PhFcεRIα_{1.172} that belongs to tetragonal space group P43, with a=b=145.08Å, c=62.74Å, a=b=g=90°, referred to herein as crystal form T1.

Protein PhFccRIa₁₋₁₇₂, having SEQ ID NO:4, was produced using techniques known to those skilled in the art by a lec1 Chinese hamster ovary (CHO) cell line transformed with a nucleic acid molecule encoding the protein, i.e., a nucleic acid molecule comprising SEQ ID NO:3. Crystals were grown in a manner similar to that described in Example 2 via vapor diffusion using a well solution of 20% to 32% PEG 10000, 0.1 M ammonium citrate pH 5.6, and 0.1 M sodium chloride, and a protein starting concentration of 5 to 10 mg/ml. Other size PEGs from 4000 to 20000 were also 30 used, as well as sodium citrate pH 5.6 as a buffer. Other salts such as sodium acetate and ammonium sulfate were also used to grow crystals. The crystal used in the structure

determination, analyzed in a manner similar to that described in Example 4, had five copies of the receptor in the crystallographic asymmetric unit and diffracted to a maximum resolution of 3.1Å. This crystal form, form T1, was refined to a crystallographic $R_{\text{free}}/R_{\text{work}}$ of 32.78%/29.19% using all the observed data |F| > 0 to 3.1Å and a non-crystallographic symmetry (NCS) restraint constant of 300 kcal/mol Å² for all atoms. There were no waters included in the model. The atomic coordinates of PhFceRI α_{1-172} , form T1, are listed in Table 5. The solvent accessibilities of the amino acids of PhFceRIa₁₋₁₇₂, form T1, are indicated in Table 9. Table 13 provides crystallographic data and model refinement statistics of PhFceRIa₁₋₁₇₂, form T1. A root mean square (rms) deviation analysis of the alpha carbon positions of PhFceRI α_{1-172} , 10 form T1, as compared to PhFceRI α_{1-176} , form M1, is shown in Table 14. The first line is an overall rms on the segments that align in space. The second two lines are the rms deviations for the loops when the molecules are superimposed according to the first line. Only one copy of model in T1 is compared because the models do not differ by much because of tight NCS restraints. 15

B. Production and description of a crystal of PhFc ϵ RI α_{1-172} that belongs to tetragonal space group P43, with a=b=150.50Å, c=74.18Å, $\alpha=\beta=\gamma=90^{\circ}$, referred to herein as crystal form T2.

Protein PhFcεRIα₁₋₁₇₂, having SEQ ID NO:4, was produced using techniques known to those skilled in the art by a lec1 Chinese hamster ovary (CHO) cell line transformed with a nucleic acid molecule encoding the protein, i.e., a nucleic acid molecule comprising SEQ ID NO:3. Crystals were grown and analyzed as described in Example 6A. The crystal used in the structure determination had five copies of the receptor in the crystallographic asymmetric unit and diffracted to a maximum resolution of 3.8Å. This crystal form, form T2, was refined to a crystallographic R_{free}/R_{work} of 30.64%/27.99% using all the observed data |F| > 0 to 3.8Å and a NCS restraint constant of 300 kcal/mol Ų for all atoms. There were no waters included in the model. The atomic coordinates of PhFceRIα₁₋₁₇₂, form T2, are listed in Table 6. The solvent accessibilities of the amino acids of PhFceRIα₁₋₁₇₂, form T2, are indicated in Table 10.

Table 13 provides crystallographic data and model refinement statistics of PhFceRIα₁₋₁₇₂,

- form T2. A rms deviation analysis of the alpha carbon positions of PhFc ϵ RI α_{1-172} , form T2, as compared to PhFc ϵ RI α_{1-176} , form M1, is shown in Table 14.
- C. Production and description of a crystal of PhFc ϵ RI α_{1-176} that belongs to monoclinic space group C2, with a=136.90Å, b=73.79Å, c=79.40Å, α = γ =90°, and β =117.74°, referred to herein as crystal form M2.

30

Protein PhFceRIa₁₋₁₇₆, having SEQ ID NO:2, was produced in T. ni Hi-5 cells as described in Example 1. Crystals were grown in a manner similar to that described in Example 2 via vapor diffusion using a well solution of 12% to 20% PEG 4000, 0.1 M HEPES (or Tris) pH 7.5, and 0 to 10% isopropanol, and a protein starting concentration of 5 to 30 mg/ml. The crystal used in the structure determination, analyzed in a manner similar to that described in Example 4, had two copies of the receptor in the crystallographic asymmetric unit and diffracted to a maximum resolution of 3.2Å. This crystal form, form M2, was refined to a crystallographic $R_{\text{free}}/R_{\text{work}}$ of 28.30%/25.69% using all the observed data |F| > 0 to 3.2Å. A NCS restraint constant of 300 kcal/mol Å² has been imposed for all atoms except certain ones in loops and crystal contacts (residues 1-3, 27-38, 41-43, 69-75, 87, 98, 111-117, 125-135, 144, 152-158 of SEQ ID NO:2) and the N-linked carbohydrate atoms. There were no waters included in the model. The atomic coordinates of PhFc ϵ RI α_{1-176} , form M2, are listed in Table 7. The solvent accessibilities of the amino acids of PhFceRIa₁₋₁₇₆, form M2, are indicated in Table 11. Table 13 provides crystallographic data and model refinement statistics of PhFceRIa₁₋₁₇₆, form M2. A rms deviation analysis of the alpha carbon positions of PhFceRI α_{1-176} , form M2, as compared to PhFceRI α_{1-176} , form M1, is shown in Table 14.

D. Production and description of a crystal of PhFceRI α_{1-172} that belongs to hexagonal space group P6₁22, with a=b=58.62Å, c=229.19Å, α = β = γ =90°, referred to herein as crystal form H1.

Protein PhFc ϵ RI α_{1-172} , having SEQ ID NO:4 except that the isoleucine at position 170 was replaced with cysteine, was produced in a manner similar to that described in Example 1, except that Spodoptera frugiperda Sf9 cells were used instead of T. ni Hi-5 cells. Crystals were grown in a manner similar to that described in Example 2 via vapor diffusion using a well solution of 20% to 30% PEG 4000, 0.1 M sodium citrate pH 5.6,

0.1 M sodium chloride, and 5-40mM Methyl-6-O-(N-heptylcarbamoyl)-a-D-glucopyranoside (HECAMEG), a protein starting concentration of 10 mg/ml. The crystal used in the structure determination, analyzed in a manner similar to that described in Example 4, had one copy of the receptor in the crystallographic asymmetric unit and diffracted to a maximum resolution of 3.2Å. This crystal form, form H1, was refined to a crystallographic R_{free}/R_{work} of 31.27%/28.78% using all the observed data |F| > 0 to 3.2Å. The atomic coordinates of PhFceRIα₁₋₁₇₂, form H1, are listed in Table 8. The solvent accessibilities of the amino acids of PhFceRIα₁₋₁₇₂, form H1, are indicated in Table 12. Table 13 provides crystallographic data and model refinement statistics of PhFceRIα₁₋₁₇₂, form H1. A rms deviation analysis of the alpha carbon positions of PhFceRIα₁₋₁₇₂, form H1, as compared to PhFceRIα₁₋₁₇₆, form M1, is shown in Table 14.

E. The principal differences in the structures from the various crystal forms occurred in the BC loop in domain 1 (the "30 loop"), the C' strand in domain 2 (the "130 region") and the carbohydrate sites. There were also smaller differences in the termini of the structures and the FG loop in domain 1 (the "72 loop").

The 30 loop showed the greatest variability across the different space groups. The density for this loop was often the poorest density in the map, suggesting that the loop may vary in conformation even within a single crystal. In T1 and T2, the density for this loop was higher than the rest (when the molecule was viewed in the normal orientation, with the FG loop of domain 2 at the top and the cleft between the domains at the bottom.) In the tetragonal cells, the 30 loop passed close to residue 51. In the two copies of the receptor in the larger monoclinic cell M2, the 30 loop was pulled down by crystallographic contacts. In these two copies, the density for the 30 loop clearly showed the loop was pulled away from the rest of the molecule to reveal an empty space inside the loop. The location of the 30 loops in H1 and M1 was intermediate to those of the tetragonal cells and M2.

The 130 strand varied across the crystal forms as well. In T1, T2, and the B copy in M2, this strand hydrogen bonded with the C strand in domain 2 to form a canonical C' strand. In the H1 form, the strand crossed over to the other side of the sheet to form a D strand. In the forms M1 and the A copy of M2, this strand was intermediate to a canonical C' and D strand.

15

WO 00/26246 PCT/US99/26203

-100-

The density at the termini tended to be poorly ordered, but the M2 crystal showed density for the N-terminus. All of the other models began at amino acid 4. The M1 and M2 models were built to residue 174 out of 176 total residues, the H1 model was built to the C-terminal residue 172, and the two tetragonal forms have models that were built to residue 171 out of 172 total residues.

While various embodiments of the present invention have been described in detail, it is apparent that modifications and adaptations of those embodiments will occur to those skilled in the art. It is to be expressly understood, however, that such modifications and adaptations are within the scope of the present invention, as set forth in the following claims.

## What is claimed is:

- 1. A three-dimensional model selected from the group consisting of: (a) a three-dimensional model of an extracellular domain of a human high affinity Fc epsilon receptor alpha chain (FcεRIα) protein, wherein said model substantially represents the atomic coordinates specified in a table selected from the group consisting of Table 1, Table 5, Table 6, Table 7, and Table 8; and (b) a three-dimensional model comprising a modification of said model of (a), wherein said modification represents a protein that binds to a Fc domain of an antibody.
- 2. A method to produce a three-dimensional model of an extracellular domain of a human FcεRIα protein, said method comprising representing amino acids of said protein at substantially the atomic coordinates specified in a table selected from the group consisting of Table 1, Table 5, Table 6, Table 7 and Table 8.
- 3. A method to produce a three-dimensional model of an antibody receptor protein other than a human FceRIa protein represented by the three-dimensional model substantially representing the atomic coordinates specified in a table selected from the group consisting of Table 1, Table 5, Table 6, Table 7 and Table 8, said method comprising homology modeling.
  - 4. An isolated crystal of an extracellular domain of a FcεRIα protein.
- 5. A method to produce an isolated crystal of an extracellular domain of a FceRIa protein, said method comprising vapor diffusion.
- 6. An isolated FceRIa protein selected from the group consisting of: (a) a protein consisting of SEQ ID NO:2; (b) a protein consisting of SEQ ID NO:4 except that the isoleucine at position 170 is replaced with a cysteine; and (c) a protein that is structurally homologous to a protein of (a) or (b), wherein said protein of (c) binds to a Fc domain of an antibody.
- 7. A method to identify a compound that inhibits the binding between an IgE antibody and a FceRIa protein, said method comprising using a three-dimensional model of an extracellular domain of a human high affinity FceRIa protein to identify said compound, wherein said model substantially represents the atomic coordinates

specified in a table selected from the group consisting of Table 1, Table 5, Table 6, Table 7 and Table 8.

- 8. A mutein that binds to a Fc domain of an antibody, wherein said mutein has an improved function compared to a protein comprising an amino acid sequence selected from the group consisting of SEQ ID NO:2 and SEQ ID NO:4, wherein said improved function is selected from the group consisting of increased stability, increased affinity for an Fc domain of an antibody, altered substrate specificity, and increased solubility, wherein said mutein is produced by a method comprising:
  - (a) analyzing a three-dimensional model substantially representing the atomic coordinates specified in a table selected from the group consisting of Table 1, Table 5, Table 6, Table 7 and Table 8 to identify at least one amino acid of the protein represented by said model which if replaced by a specified amino acid would effect said improved function of said protein; and
  - (b) replacing said identified amino acid(s) to produce said mutein having said improved function.
  - 9. A mutein having an improved function compared to an unmodified FcεRIα protein, wherein said improved function is selected from the group consisting of increased stability, increased affinity for an Fc domain of an antibody, altered substrate specificity, and increased solubility, wherein the amino acid sequence of said mutein differs in at least one position from the amino acid sequence of said unmodified protein, said position being in a region selected from the group consisting of a crystal contact cluster, a tryptophan-containing hydrophobic ridge, a FG loop in D2, a D1D2 interface, a cleft between D1 and D2, a domain 1, a domain 2, a hydrophobic core, a A'B loop of D1, a EF loop of D1, a BC loop of D2, a C strand of D2, a CC' loop of D2, a C'E loop of D2, a strand of D2, the amino terminal five residues of said protein, and the carboxyl terminal five residues of said protein.
    - 10. A method to improve a function of a FceRIa protein, said improved function being selected from the group consisting of increased stability, increased affinity for an Fc domain of an antibody, altered substrate specificity, and increased solubility, said method comprising:

	· ·	

- (a) analyzing a three-dimensional model of an extracellular domain of a human high affinity FcεRlα protein substantially representing the atomic coordinates specified in a table selected from the group consisting of Table 1, Table 5, Table 6, Table 7 and Table 8 to identify at least one amino acid of said protein which if replaced by a specified amino acid improves at least one of said functions of said protein; and
- (b) replacing said identified amino acid(s) to produce a mutein having at least one of said improved functions.
- 11. An isolated FceRIa protein selected from the group consisting of: a crystal contact cluster involved in IgE binding; a tryptophan-containing hydrophobic ridge; a FG loop in D2; a D1D2 interface; a cleft between D1 and D2; a domain 1; a domain 2; a hydrophobic core; a A'B loop of D1; a EF loop of D1; a BC loop of D2; a C strand of D2; a CC' loop of D2; a C'E loop of D2; and a strand of D2.
- 12. The invention of Claim 1, 2, 3, 7, 8 or 10, wherein said model is represented by a method selected from the group consisting of listing the coordinates of all atoms comprising said model, providing a physical three-dimensional model, imaging said model on a computer screen, providing a picture of said model, and deriving a set of coordinates based of a picture of said model.
- 13. The invention of Claim 1, 2, 3, 7, 8 or 10, wherein said model identifies the solvent accessibility of amino acid residues of said protein listed in a table selected from the group consisting of Table 2, Table 9, Table 10, Table 11 and Table 12.
- 14. The invention of Claim 1, 2, 3, 7, 8 or 10, wherein said model represents a protein that binds to a Fc domain of an IgE antibody with an affinity that is at least equivalent to the affinity of the extracellular domain of human FceRIa for an IgE antibody selected from the group consisting of a human IgE antibody, a canine IgE antibody, a feline IgE antibody, an equine IgE antibody, a rat IgE antibody, and a murine IgE antibody.
- 15. The invention of Claim 1, 2, 3, 7, 8 or 10, wherein said model represents a protein that selectively binds to a mammalian antibody selected from the group consisting of an IgE antibody and an IgG antibody.

- 16. The invention of Claim 1, 2, 3, 7, 8 or 10, wherein said model represents an extracellular domain of a protein selected from the group consisting of a human FceRIa protein, a canine FceRIa protein, a feline FceRIa protein, an equine FceRIa protein, a murine FceRIa protein, and a rat FceRIa protein.
- 17. The invention of Claim 1, 2, 3, 7, 8 or 10, wherein said model comprises a three-dimensional model of an extracellular antibody binding domain of an antibody receptor protein other than human FceRIa.
- 18. The invention of Claim 17, wherein said model is produced by incorporating all or any part of the amino acid sequence of said other antibody receptor protein into a three-dimensional model of said extracellular domain of said human FceRIa protein to produce said model of said other antibody receptor protein.
- 19. The invention of Claim 1, 2, 3, 7, 8 or 10, wherein said model represents an IgE binding domain.
- 20. The invention of Claim 1, 2, 3, 7, 8 or 10, wherein said model is produced by a method comprising:
  - (a) crystallizing an extracellular domain of a human FceRIa protein;
  - (b) collecting X-ray diffraction data from said crystallized protein; and
  - (c) determining said model from said data and amino acid sequence of said protein.
- 21. The invention of Claim 20, wherein said protein has an amino acid sequence selected from the group consisting of SEQ ID NO:2, SEQ ID NO:4 and SEQ ID NO:4 except that the isoleucine at position 170 is replaced with a cysteine.
- 22. The invention of Claim 1, 2, 3, 7, 8 or 10, wherein said model has a three-dimensional structure comprising atomic coordinates that have a root mean square deviation of protein backbone atoms of less than 10 angstroms when superimposed on said three-dimensional model substantially represented by the atomic coordinates specified in a table selected from the group consisting of Table 1, Table 5, Table 6, Table 7, and Table 8.

- 23. The invention of Claim 1, wherein said modification has an amino acid sequence that shares at least about 30% amino acid sequence homology with a FceRIa protein having an amino acid sequence selected from the group consisting of SEQ ID NO:2 and SEQ ID NO:4.
- 24. The invention of Claim 1 or 3, wherein said model represents a FcεRIα protein having increased stability compared to the stability of a human FcεRIα protein having an amino acid sequence selected from the group consisting of SEQ ID NO:2 and SEQ ID NO:4.
- 25. The invention of Claim 1 or 3, wherein said model represents a Fc $\epsilon$ RI $\alpha$  protein having increased affinity for IgE compared to the affinity of a human Fc $\epsilon$ RI $\alpha$  protein having an amino acid sequence selected from the group consisting of SEQ ID NO:2 and SEQ ID NO:4 for IgE.
- 26. The invention of Claim 1 or 3, wherein said model represents a FcεRIα protein having altered substrate affinity compared to the affinity of a human FcεRIα protein having an amino acid sequence selected from the group consisting of SEQ ID NO:2 and SEQ ID NO:4 for IgE.
- 27. The invention of Claim 1 or 3, wherein said model comprises a three-dimensional model of a FcεRIα protein having increased solubility compared to the solubility of a human FcεRIα protein having an amino acid sequence selected from the group consisting of SEQ ID NO:2 and SEQ ID NO:4.
- 28. The invention of Claim 1, 2 or 3, wherein said model is used to identify an inhibitor of the selective binding between a FceRIa protein and an IgE antibody.
- 29. The invention of Claim 1, 2, 3, 7, 8 or 10, wherein said model identifies crystal contacts between a FcεRIα protein and a Fc domain of an IgE antibody.
- 30. The invention of Claim 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 or 11, wherein domain 1 and domain 2 are oriented in a manner as specified by the structural coordinates specified in a table selected from the group consisting of Table 1, Table 5, Table 6, Table 7 and Table 8.
- 31. The invention of Claim 1, 2, 3, 7, 8, or 10, wherein said model identifies amino acids in the D1D2 interface.

<b>5</b> ]		

- 32. The invention of Claim 3, wherein said method of homology modeling comprises incorporating at least a portion of the amino acid sequence of said other antibody receptor protein into said three-dimensional model substantially representing the atomic coordinates specified in a table selected from the group consisting of Table 1, Table 5, Table 6, Table 7 and Table 8 to produce said model of said other antibody receptor protein.
- 33. The invention of Claim 1, 2, 3, 4, 5, or 6, wherein said protein has an amino acid sequence selected from the group consisting of SEQ ID NO:2, SEQ ID NO:4, and SEQ ID NO:4 except that the isoleucine at position 170 is replaced with a cysteine.
- 34. The invention of Claim 4 or 5, wherein said crystal belongs to a space group selected from the group consisting of monoclinic space group C2, hexagonal space group P6₁22, and tetragonal space group P4₃.
- 35. The invention of Claim 4 or 5, wherein said crystal is selected from the group consisting of: a monoclinic space group C2 having cell dimensions of 88.6 angstroms x 69.6 angstroms x 49.3 angstroms, alpha=gamma=90.0 degrees, beta=116.69 degrees; a monoclinic space group C2 having cell dimensions of 136.02 angstroms x 75.01 angstroms x 79.28 angstroms, alpha=gamma=90 degrees, beta=117.8 degrees; a monoclinic space group C2 having cell dimensions of 136.90 angstroms x 73.79 angstroms x 79.40 angstroms, alpha=gamma=90 degrees, beta=117.74 degrees; a tetragonal space group P4, having cell dimensions of 145.08 angstroms x 145.08 angstroms x 62.74 angstroms, alpha=beta=gamma=90 degrees; a tetragonal space group P4, having cell dimensions of 150.50 angstroms x 74.18 angstroms, alpha=beta=gamma=90 degrees; a hexagonal space group P6,22 having cell dimensions of 58 angstroms x 58 angstroms x 226 angstroms, alpha=beta=90 degrees, gamma=120 degrees; and a hexagonal space group P6,22 having cell dimensions of 58.62 angstroms x 229.19 angstroms, alpha=beta=90 degrees, gamma=120 degrees.
  - 36. The invention of Claim 4, 5, 6, or 11, wherein said protein is produced in insect cells or Chinese hamster ovary cells.

- 37. The invention of Claim 4 or 5, wherein said crystal diffracts X-rays to a resolution selected from the group consisting of about 2.4 angstroms, about 3.1 angstroms, about 3.2 angstroms, and about 3.8 angstroms.
- 38. The invention of Claim 1, 3, 4, 5, 6, 7, 9 or 11, wherein said protein represented by said modification of Claim 1, said antibody receptor protein of Claim 3, or said FcεRIα protein of Claim 4, 5, 6, 7, 9 or 11 is selected from the group consisting of a human FcεRIα protein, a feline FcεRIα protein, a canine FcεRIα protein, an equine FcεRIα protein, a murine FcεRIα protein, and a rat FcεRIα protein.
- 39. A nucleic acid molecule comprising a nucleic acid sequence that encodes a protein selected from the group consisting of said protein of Claim 6 or 11 and said mutein of Claim 8, 9, or 10.
  - 40. A recombinant molecule comprising a nucleic acid sequence of Claim 39.
  - 41. A recombinant virus comprising a nucleic acid sequence of Claim 39.
  - 42. A recombinant cell comprising a nucleic acid sequence of Claim 39.
- 43. A method to produce a protein comprising culturing a recombinant cell of Claim 42.
- 44. An inhibitory compound identified in accordance with the method of Claim 7.
- 45. A therapeutic composition comprising an inhibitory compound of Claim 44.
- 46. A method to protect an animal from allergy, said method comprising administering to said animal an inhibitory compound of Claim 44.
- 47. The invention of Claim 7, 44, 45, or 46, wherein said compound interacts with a region of said model selected from the group consisting of the IgE binding domain, the D1D2 interface, and the cleft between domain 1 and domain 2.
- 48. The invention of Claim 7, 44, 45, or 46, wherein said compound interacts with a region of said model selected from the group consisting of a A'B loop of domain 1, a EF loop of domain 1, a BC loop of domain 2, a C strand of domain 2, a CC' loop of domain 2, a C'E loop of domain 2, a F strand of domain 2, a FG loop of domain 2, and a tryptophan-containing hydrophobic ridge.

- 32. The invention of Claim 3, wherein said method of homology modeling comprises incorporating at least a portion of the amino acid sequence of said other antibody receptor protein into said three-dimensional model substantially representing the atomic coordinates specified in a table selected from the group consisting of Table 1, Table 5, Table 6, Table 7 and Table 8 to produce said model of said other antibody receptor protein.
- 33. The invention of Claim 1, 2, 3, 4, 5, or 6, wherein said protein has an amino acid sequence selected from the group consisting of SEQ ID NO:2, SEQ ID NO:4, and SEQ ID NO:4 except that the isoleucine at position 170 is replaced with a cysteine.
- 34. The invention of Claim 4 or 5, wherein said crystal belongs to a space group selected from the group consisting of monoclinic space group C2, hexagonal space group P6,22, and tetragonal space group P4₃.
- 35. The invention of Claim 4 or 5, wherein said crystal is selected from the group consisting of: a monoclinic space group C2 having cell dimensions of 88.6 angstroms x 69.6 angstroms x 49.3 angstroms, alpha=gamma=90.0 degrees, beta=116.69 degrees; a monoclinic space group C2 having cell dimensions of 136.02 angstroms x 75.01 angstroms x 79.28 angstroms, alpha=gamma=90 degrees, beta=117.8 degrees; a monoclinic space group C2 having cell dimensions of 136.90 angstroms x 73.79 angstroms x 79.40 angstroms, alpha=gamma=90 degrees, beta=117.74 degrees; a tetragonal space group P43 having cell dimensions of 145.08 angstroms x 145.08 angstroms x 62.74 angstroms, alpha=beta=gamma=90 degrees; a tetragonal space group P43 having cell dimensions x 150.50 angstroms x 74.18 angstroms, alpha=beta=gamma=90 degrees; a hexagonal space group P6122 having cell dimensions of 58 angstroms x 58 angstroms x 226 angstroms, alpha=beta=90 degrees, gamma=120 degrees; and a hexagonal space group P6122 having cell dimensions of 58.62 angstroms x 229.19 angstroms, alpha=beta=90 degrees, gamma=120 degrees.
- 36. The invention of Claim 4, 5, 6, or 11, wherein said protein is produced in insect cells or Chinese hamster ovary cells.

WO 00/26246 PC 1/US!

49. The invention of Claim 7, 44, 45, or 46, wherein said compound interacts with a region of said model in which N-linked glycosylation sites are absent.

- 50. The invention of Claim 7, 44, 45, or 46, wherein said compound interacts with an amino acid selected from the group consisting of: (a) a residue having a position in SEQ ID NO:2 or SEQ ID NO:4 selected from the group consisting of position 87, 115, 117, 118, 120-123, 128, 129, 131, 149, 153, 155 and 159; and (b) a surface residue within about 10 angstroms of any of said residues of (a).
- 51. The invention of Claim 7, 44, 45, or 46, wherein said compound interacts with an amino acid selected from the group consisting of: (a) a residue having a position in SEQ ID NO:2 or SEQ ID NO:4 selected from the group consisting of position 87, 117, 121, 123, 128, and 159; and (b) a surface residue within about 10 angstroms of any of said residues of (a).
  - 52. The invention of Claim 7, wherein said method comprises:
  - (a) generating said model, or a model of an IgE binding domain thereof, on a computer screen;
    - (b) generating the spacial structure of a compound to be tested; and
  - (c) testing to determine if said compound interacts with said IgE binding domain, wherein such an interaction indicates that said compound is capable of inhibiting said binding of an IgE antibody to a FceRIa protein.
- 53. The invention of Claim 52, wherein said step (a) includes the step of identifying one or more amino acid(s) in the IgE binding domain of said model that interact directly with the Fc domain of an IgE antibody when said Fc domain binds to said IgE binding domain.
- 54. The invention of Claim 53, wherein said compound interacts directly with one or more of said amino acid(s).
  - 55. A diagnostic reagent comprising a mutein of Claim 8, 9 or 10.
  - 56. A therapeutic composition comprising a mutein of Claim 8, 9 or 10.
- 57. A method to use a mutein of Claim 8, 9 or 10, wherein said method is selected from the group consisting of: (a) a method to protect an animal from allergy, said method comprising administering a therapeutic composition comprising said mutein

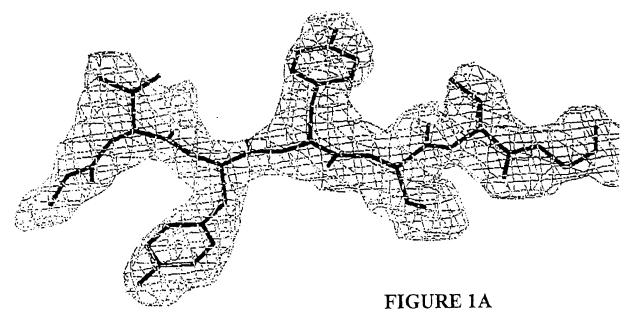

to said animal; (b) a method to detect allergy, or susceptibility thereto, in an animal, said method comprising using said mutein to detect said allergy; and (c) a method to enhance the performance of an IgE binding assay, said method comprising incorporating into said assay said mutein.

- 58. The invention of Claim 8 or 10, wherein said step of replacing does not substantially disrupt the three-dimensional structure of said protein.
- 59. The invention of Claim 8, 9, 10, 55, 56 or 57, wherein said mutein has an increased stability compared to an unmodified antibody receptor protein.
- 60. The invention of Claim 8, 9, 10, 55, 56 or 57, wherein said mutein has an increased shelf-life compared to an unmodified antibody receptor protein.
- The invention of Claim 8, 9, 10, 55, 56 or 57, wherein said mutein has a  $K_A$  for said Fc domain of at least about 3 x 10° liters/mole.
- 62. The invention of Claim 8, 9, 10, 55, 56 or 57, wherein said mutein has a k, for said Fc domain of at least about 1 x 10⁵ liters/mole-second.
- 63. The invention of Claim 8, 9, 10, 55, 56 or 57, wherein said mutein has a  $k_d$  for said Fc domain of less than or equal to 3 x  $10^{-5}$ /second.
- 64. The invention of Claim 8, 9 or 10, wherein said antibody is an IgE antibody.
- 65. The invention of Claim 8, 55, 56 or 57, wherein said mutein is produced by a method comprising:
  - (a) comparing the IgE binding domain on said model with amino acid sequence of an antibody receptor protein with an improved function to identify at least one amino acid segment of said antibody receptor protein with said improved function that if incorporated into said FcεRIα protein represented by said model would give said FcεRIα protein said improved function; and
  - (b) incorporating said segment into said FceRIa protein, thereby producing a mutein with said improved function.
- 66. The invention of Claim 8, 10, 55, 56 or 57, wherein said mutein is produced by a method comprising:

- (a) using said model to identify a three-dimensional arrangement of residues that can be randomized by mutagenesis to allow the construction of a library of molecules from which an improved function can be selected; and
- (b) identifying at least one member of said mutagenized library having said improved function.
- 67. The invention of Claim 8, 9, 10, 55, 56 or 57, wherein said mutein is produced by a method comprising:
  - (a) effecting random mutagenesis of nucleic acid molecules encoding a target of a FcεRIα protein as identified by analyzing a model of that protein;
  - (b) cloning said mutagenized nucleic acid molecules into a phage display library, wherein said phage display library expresses said target; and
  - (c) identifying at least one member of the library that expresses said target, said target having an improved function.
- 68. The invention of Claim 67, wherein said target comprises an IgE binding domain and wherein said improved function comprises increased affinity of said domain for an antibody.
- 69. The invention of Claim 8 or 10, wherein said step of replacing is selected from the group consisting of:
  - (a) replacing at least one amino acid in at least one non-constrained loop of domain 1 in an area proximal to the FceRI gamma chain putative binding site;
  - (b) joining an amino-terminal amino acid residue to a carboxylterminal amino acid residue of an extracellular domain of a FcεRIα protein;
  - (c) replacing at least one amino acid site with an amino acid suitable for derivatization;
  - (d) replacing at least one pair of amino acids of said protein with a cysteine pair to enable the formation of a disulfide bond that stabilizes said mutein;
  - (e) removing at least a portion of the region between the B strand and C strand of domain 1;

- (f) removing at least a portion of the region between the C strand and E strand of domain 1;
- (g) replacing at least one amino acid in the IgE binding domain in order to increase the affinity between an IgE antibody and said protein;
- (h) replacing at least one amino acid of said protein with an amino acid such that said replacement decreases the entropy of unfolding of said protein;
- (i) replacing at least one amino acid of said protein selected from the group consisting of asparagines and glutamines with an amino acid that is less susceptible to deamidation than is said amino acid to be replaced;
- (j) replacing at least one amino acid of said protein selected from the group consisting of methionines, histidines and tryptophans with an amino acid that is less susceptible to an oxidation or reduction reaction than is said amino acid to be replaced;
- (k) replacing at least one arginine of said protein with an amino acid that is less susceptible to dicarbonyl compound modification than is said amino acid to be replaced;
- (l) replacing at least one amino acid of said protein susceptible to reaction with a reducing sugar sufficient to reduce said protein function with an amino acid less susceptible to said reaction;
- (m) replacing at least one amino acid of said protein with an amino acid capable of increasing the stability of the inner core of said protein;
- (n) replacing at least one amino acid of said protein with at least one N-linked glycosylation site;
- (o) replacing at least one N-linked glycosylation site of said protein with at least one amino acid that does not comprise an N-linked glycosylation site; and
- (p) replacing at least one amino acid of said protein with an amino acid that reduces aggregation of said protein.

70. The invention of Claim 8, 9, 10, 55, 56 or 57, further comprising a substance attached to an amino acid of said mutein such that said substance does not substantially interfere with the antibody binding activity of said protein.

## INTERNATIONAL SEARCH REPORT

PCT/US 99/26203

Box I Observations where certain claims were found unsearchable (Continuation of Item 1 of first sheet)
This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:
1. X Claims Nos.: because they relate to subject matter not required to be searched by this Authority, namely: see FURTHER INFORMATION sheet PCT/ISA/210
2. X Claims Nos.: because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:  see FURTHER INFORMATION sheet PCT/ISA/210
3. Claims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).
Box II Observations where unity of invention is lacking (Continuation of Item 2 of first sheet)
This International Searching Authority found multiple inventions in this International application, as follows:
As all required additional search fees were timely paid by the applicant, this international Search Report covers all searchable claims.
2. As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:
Remark on Protest  The additional search fees were accompanied by the applicant's protest.  No protest accompanied the payment of additional search fees.

International Application No. PCT/US 99 26203

#### FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

Continuation of Box I.1

Claims Nos.: 1-3,17,18,23-28,32(all not) and 12-16,19-22,29-31,33,38(all partially)

The claims 1-3,12-33 and 38 relate to or comprise a 3-D model or its production which is considered to be subject-matter encompassed by Rule 39.1(v) and/or (vi) PCT, being subject-matter which the ISA is not required to search under Art.17(2)(a)(i) PCT.

Continuation of Box I.2

Claims Nos.: 8-10,44-46,55-70(all not) and 4,5,7,11,12-16,19-22,29-31,33-43,47-54(all partially)

Present claims 4,5,7-16,19-22,29-31,33-43 relate to or comprise compounds or their use defined by reference to a desirable characteristic or property: according to the description the human high affinity Fc epsilon receptor alpha chain is only defined as the portion of the FceRI alpha chain that is exposed to the environment outside the cell and that binds to the Fc domain of an IgE antibody (see page 8, lines 13-22), muteins thereof which have only be defined by desired properties or DNA coding therefore.

The claims cover all compounds having this characteristic or property, whereas the application provides support within the meaning of Article 6 PCT and/or disclosure within the meaning of Article 5 PCT for only a very limited number of such compounds (see claim 6 and the examples). In the present case, the claims so lack support, and the application so lacks disclosure, that a meaningful search over the whole of the claimed scope is impossible. Independent of the above reasoning, the claims also lack clarity (Article 6 PCT).

An attempt is made to define compounds by reference to a result to be achieved. Again, this lack of clarity in the present case is such as to render a meaningful search over the whole of the claimed scope impossible.

Furthermore the claims 44-70 relate to or encompass compounds that have only be defined by their ability to inhibit the binding between an IgE antibody and a FceRIalpha protein. The same objections under Art.6 PCT are also applicable, mutatis mutandis, to the claims 44-70. Consequently, the search has been carried out for those parts of the claims which appear to be clear, supported and disclosed, namely those parts relating to the compounds defined in claim 6, that is the compounds having the SEQ ID No 2 and SEQ ID No 4 wherein Ile in position 170 is replaced with Cys and crystals of said compounds and of the compound defined by SEQ ID No.4.

The applicant's attention is drawn to the fact that claims, or parts of claims, relating to inventions in respect of which no international search report has been established need not be the subject of an international preliminary examination (Rule 66.1(e) PCT). The applicant

International Application No. PCT/US 99 &6203

# FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

is advised that the EPO policy when acting as an International Preliminary Examining Authority is normally not to carry out a preliminary examination on matter which has not been searched. This is the case irrespective of whether or not the claims are amended following receipt of the search report or during any Chapter II procedure.
